Preface

Oracle TimesTen In-Memory Database is a memory-optimized relational database. Deployed in the application tier, TimesTen operates on databases that fit entirely in physical memory using standard SQL interfaces. High availability for the in-memory database is provided through real-time transactional replication.

TimesTen supports a variety of programming interfaces, including PL/SQL (Oracle procedural language extension for SQL), ODBC (Open Database Connectivity), JDBC (Java Database Connectivity), OCI (Oracle Call Interface), Pro*C/C++ (Oracle precompiler for embedded SQL and PL/SQL instructions in C or C++ code), TTClasses (TimesTen C++ Interface Classes), and ODP.NET (Oracle Data Provider for .NET).

This document covers TimesTen support for ODBC, OCI, and Pro*C/C++.

The following topics are discussed in the preface:

- Audience
- Related documents
- Conventions
- Documentation Accessibility

Audience

This guide is for anyone developing or supporting applications that use TimesTen through ODBC, OCI, or Pro*C/C++.

In addition to familiarity with the particular programming interface you use, you should be familiar with TimesTen, SQL (Structured Query Language), and database operations.

Related documents

TimesTen documentation is available on the product distribution media and on the Oracle Technology Network:

http://www.oracle.com/technetwork/products/timesten/documentation/

Oracle documentation is also available on the Oracle Technology network. This may be especially useful for Oracle features that TimesTen supports but does not attempt to fully document, such as OCI and Pro*C/C++:

http://www.oracle.com/technetwork/database/enterprise-edition/documentation/

In particular, the following Oracle documents may be of interest.

- *Oracle Call Interface Programmer's Guide*

- *Pro*C/C++ Programmer's Guide*

- *Oracle Database Globalization Support Guide*

- *Oracle Database Net Services Administrator's Guide*

- *Oracle Database SQL Language Reference*

This manual frequently refers to ODBC API reference documentation for further information. This is available from Microsoft or a variety of third parties. For example:

http://msdn.microsoft.com/en-us/library/ms714562(VS.85).aspx

Note that TimesTen supports ODBC 2.5, Extension Level 1, with additional features for Extension Level 2 where those features are included in Chapter 10, "TimesTen ODBC Functions and Options".

Conventions

TimesTen supports multiple platforms. Unless otherwise indicated, the information in this guide applies to all supported platforms. The term Windows applies to all supported Windows platforms. The term UNIX applies to all supported UNIX and Linux platforms. Refer to the "Platforms" section in *Oracle TimesTen In-Memory Database Release Notes* for specific platform versions supported by TimesTen.

> **Note:** In TimesTen documentation, the terms "data store" and "database" are equivalent. Both terms refer to the TimesTen database unless otherwise noted.

This document uses the following text conventions:

Convention	Meaning
italic	Italic type indicates terms defined in text, book titles, or emphasis.
monospace	Monospace type indicates code, commands, URLs, function names, attribute names, directory names, file names, text that appears on the screen, or text that you enter.
italic monospace	Italic monospace type indicates a placeholder or a variable in a code example for which you specify or use a particular value. For example:
	Driver=*install_dir*/lib/libtten.sl
	Replace *install_dir* with the path of your TimesTen installation directory.
[ ]	Square brackets indicate that an item in a command line is optional.
{ }	Curly braces indicated that you must choose one of the items separated by a vertical bar (	) in a command line.
		A vertical bar (or pipe) separates alternative arguments.
. . .	An ellipsis (. . .) after an argument indicates that you may use more than one argument on a single command line. An ellipsis in a code example indicates that what is shown is only a partial example.
%	The percent sign indicates the UNIX shell prompt.

In addition, TimesTen documentation uses the following special conventions.

Convention	Meaning
install_dir	The path that represents the directory where TimesTen is installed.
TTinstance	The instance name for your specific installation of TimesTen. Each installation of TimesTen must be identified at installation time with a unique instance name. This name appears in the installation path.
bits or *bb*	Two digits, either 32 or 64, that represent either a 32-bit or 64-bit operating system.
release or *rr*	The first three parts in a release number, with or without dots. The first three parts of a release number represent a major TimesTen release. For example, 1122 or 11.2.2 represents TimesTen 11*g* Release 2 (11.2.2).
DSN	TimesTen data source name (for the TimesTen database).

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

What's New

This section summarizes new features and functionality of Oracle TimesTen In-Memory Database 11*g* Release 2 (11.2.2) that are documented in this guide, providing links into the guide for more information.

New features in Release 11.2.2.4.0

- This release of the document provides information about TimesTen support for the ODBC `SQLGetInfo` and `SQLColAttributes` functions.

  See Chapter 10, "TimesTen ODBC Functions and Options".

New features in Release 11.2.2.2.0

- `SQLCancel` support enhancements

  A previous restriction for canceling an operation running on a statement handle on another thread has been removed.

  See "Supported ODBC functions" on page 10-1 for further information on TimesTen support of the ODBC `SQLCancel` function.

New features in Release 11.2.2.0.0

- LOB support

  TimesTen supports LOBs (large objects). This includes CLOBs (character LOBs), NCLOBs (national character LOBs), and BLOBs (binary LOBs).

  For details of support in the C APIs, refer to "Working with LOBs" on page 2-23 (general LOB overview and support for ODBC), "LOBs in TimesTen OCI" on page 3-19, and "LOBs in TimesTen Pro*C/C++" on page 4-10.

- Associative array binding

  Associative arrays, formerly known as index-by tables or PL/SQL tables, are supported as `IN`, `OUT`, or `IN OUT` bind parameters in TimesTen PL/SQL, such as from an OCI or Pro*C/C++ application. (This is not relevant for TimesTen ODBC applications.) This enables arrays of data to be passed efficiently between an application and the database.

  See "Associative array bindings in TimesTen OCI" on page 3-13 and "Associative array bindings in TimesTen Pro*C/C++" on page 4-9.

- ODBC "W" functions

TimesTen now supports some "W" (wide-character) versions of ODBC functions. For example, `SQLGetConnectOptionW` is supported in addition to `SQLGetConnectOption`.

See "Supported ODBC functions" on page 10-1.

■ Deprecation of non-persistent XLA

Features for XLA non-persistent mode have been deprecated and removed from the documentation. Use utilities and APIs for persistent XLA only.

1

C Development Environment

This chapter provides information about the C development environment and related considerations for developing TimesTen applications. The following topics are covered:

- Setting the environment for development
- Linking options
- Compiling and linking applications
- About the TimesTen C demos

Setting the environment for development

Environment variable settings for TimesTen are discussed in "Environment variables" in the *Oracle TimesTen In-Memory Database Installation Guide*.

On UNIX platforms, set the environment for TimesTen by using one of the following scripts:

```
install_dir/bin/ttenv.sh
install_dir/bin/ttenv.csh
```

On Windows, set the environment during installation or use the following:

```
install_dir\bin\ttenv.bat
```

> **Notes:**
>
> - The `ttenv` scripts also configure access to the Oracle Instant Client, required for OCI programming.
>
> - You can optionally use the appropriate `ttquickstartenv` script instead of `ttenv`. This is a superset of `ttenv` that also sets up the TimesTen Quick Start demo environment.
>
> - To ensure proper generation of OCI and Pro*C/C++ programs to be run on TimesTen, do not set `ORACLE_HOME` (or unset it if it was set previously) for OCI and Pro*C/C++ compilations.

Linking options

A TimesTen application can link specifically with the TimesTen ODBC direct driver or ODBC client driver without a driver manager, or can link with a driver manager.

Linking without an ODBC driver manager

Applications to be used solely with TimesTen can link specifically with either the TimesTen ODBC direct driver or the ODBC client driver, without a driver manager. This avoids the performance overhead of a driver manager and is the simplest way to access TimesTen. However, developers of applications linked without a driver manager should be aware of the following issues.

- The application can only connect to a DSN that uses the driver with which it is linked. It cannot connect to a database of any other vendor, nor can it connect to a TimesTen DSN of a different TimesTen driver or a different version or type.

- Windows ODBC tracing is not available.

- The ODBC cursor library is not available.

- Applications cannot use ODBC functions that are usually implemented by a driver manager, such as `SQLDataSources` and `SQLDrivers`.

- Applications that use `SQLCancel` to close a cursor instead of `SQLFreeStmt(...,` `SQL_CLOSE)` will receive a return code of `SQL_SUCCESS_WITH_INFO` and a SQL state of `01S05`. This warning is intended to be used by the driver manager to manage its internal state. Applications should treat this warning as success.

Linking with an ODBC driver manager

Applications that link with the ODBC driver manager can connect to any DSN that references an ODBC driver and can even connect simultaneously to multiple DSNs that use different ODBC drivers. Note, however, that driver managers are not available by default on most non-Windows platforms. In addition, using a driver manager may add significant synchronization overhead to every ODBC function call and has the following limitations:

- The TimesTen option `TT_PREFETCH_COUNT` cannot be used with applications that link with a driver manager. For more information on using `TT_PREFETCH_COUNT`, see "Prefetching multiple rows of data" on page 2-11.

- Applications cannot set or reset the TimesTen-specific `TT_PREFETCH_CLOSE` connection option. For more information about using the `TT_PREFETCH_CLOSE` connection option, see "Enable TT_PREFETCH_CLOSE for Serializable transactions" in the *Oracle TimesTen In-Memory Database Operations Guide*.

- Transaction Log API (XLA) calls cannot be used when applications are linked with a driver manager.

- The ODBC C types `SQL_C_BIGINT`, `SQL_C_TINYINT`, and `SQL_C_WCHAR` are not supported for an application linked with a driver manager when used with TimesTen. You cannot call methods that have any of these types in their signatures.

- The driver manager does not support LOB locator APIs or LOB data types, which are not part of the ODBC standard. However, you can use the LOB simple data interface or piecewise data interface as documented in "Working with LOBs" on page 2-23.

> **Note:** TimesTen supplies a driver manager for both Windows and UNIX with the Quick Start sample applications. This driver manager is not fully supported. It supports only the TimesTen direct driver and client driver and does not have the functionality or performance limitations described above. Applications that must concurrently use both direct connections and client/server connections to TimesTen can use this driver manager to achieve this with very little impact on performance.

Compiling and linking applications

This section discusses compiling and linking C applications on Windows or UNIX.

Compiling and linking applications on Windows

WINDOWS To compile TimesTen applications on Windows, you are not required to specify the location of the ODBC include files. These files are included with Microsoft Visual C++. However, you must indicate the location of TimesTen include files by using the /I compiler option. (See "TimesTen include files" on page 2-7.)

The Makefile in Example 1–1 shows how to build a TimesTen application on Windows systems. This example assumes that *install_dir*\lib has already been added to the LIB environment variable.

Example 1–1   Building a TimesTen application in Windows

```
CFLAGS = "/Iinstall_dir\"
LIBSDM = ODBC32.LIB
LIBS = tten1122.lib ttdv1122.lib
LIBSDEBUG = tten1122d.lib ttdv1122d.lib
LIBSCS = ttclient1122.lib

# Link with the ODBC driver manager
appldm.exe:appl.obj
            $(CC) /Feappldm.exe appl.obj $(LIBSDM)

# Link directly with the TimesTen
# ODBC production driver
appl.exe:appl.obj
          $(CC) /Feappl.exe appl.obj\
          $(LIBS)

# Link directly with the TimesTen
# ODBC debug driver
appldebug.exe:appl.obj
              $(CC) /Feappldebug.exe appl.obj\
              $(LIBSDEBUG)

# Link directly with the TimesTen
# ODBC client driver
applcs.exe:appl.obj
           $(CC) /Feapplcs.exe appl.obj\
           $(LIBSCS)
```

Compiling and linking applications on UNIX

On UNIX platforms:

- Compile TimesTen applications using the TimesTen header files from the TimesTen installation directory.

- Link with the TimesTen ODBC direct driver or client driver, each of which is provided as a shared library.

On UNIX, applications using the SQL_C_ULONG, SQL_C_SLONG, SQL_C_USHORT or SQL_C_SSHORT ODBC data types must specify the TT_USE_ALL_TYPES preprocessor option while compiling. This is typically done using the -DTT_USE_ALL_TYPES C compiler option.

To use the TimesTen include files, add the following to the C compiler command, where *install_dir* is the TimesTen installation directory path:

```
-Iinstall_dir/
```

To link with the TimesTen ODBC direct driver, add the following to the link command:

```
-Linstall_dir/lib -ltten
```

The -L option tells the linker to search the TimesTen lib directory for library files. The -ltten option links in the TimesTen ODBC direct driver.

To link with the TimesTen ODBC client driver, add the following to the link command:

```
-Linstall_dir/lib -lttclient
```

On Solaris, the default TimesTen ODBC client driver was compiled with Studio 11. The library enables you to link an application compiled with the Sun Studio 11 C/C++ compiler directly with the TimesTen client.

On AIX, when linking applications with the TimesTen ODBC client driver, the C++ runtime library must be included in the link command (because the client driver is written in C++ and AIX does not link it automatically) and must follow the client driver:

```
-Linstall_dir/lib -lttclient -lC_r
```

You can use Makefiles in subdirectories under the quickstart/sample_code directory, or you can use Example 1–2 to guide you in creating your own Makefile.

Example 1–2   Makefile to link the application

```
CFLAGS = -Iinstall_dir/
LIBS = -Linstall_dir/lib -ltten
LIBSDEBUG = -Linstall_dir/lib -lttenD
LIBSCS = -Linstall_dir/lib -lttclient

# Link directly with the TimesTen
# ODBC production driver
appl:appl.o
     $(CC) -o appl appl.o $(LIBS)

# Link directly with the TimesTen ODBC debug driver
appldebug:appl.o
     $(CC) -o appldebug appl.o $(LIBSDEBUG)
```

```
# Link directly with the TimesTen client driver
applcs:appl.o
    $(CC) -o applcs appl.o $(LIBSCS)
```

> **Notes:**
>
> - To directly link your application to the debug TimesTen ODBC driver, substitute `-lttenD` for `-ltten` on the link line.
>
> - On Solaris, when compiling with Sun C/C++ compilers, TimesTen applications must be compiled and linked with the `-mt` option.

About the TimesTen C demos

After you have configured your C environment, you can confirm that everything is set up correctly by compiling and running TimesTen Quick Start demo applications. Refer to the Quick Start welcome page at *install_dir*/quickstart.html, especially the links under SAMPLE PROGRAMS, for information on the following topics.

- Demo schema and setup: The build_sampledb script (.sh on UNIX or .bat on Windows) creates a sample database and demo schema. You must use this before you start using the demos.

- Demo environment and setup: The ttquickstartenv script (.sh or .csh on UNIX or .bat on Windows), a superset of the ttenv script generally used for TimesTen setup, sets up the demo environment. You must use this each time you enter a session where you want to compile or run any of the demos.

- Demos and setup: TimesTen provides demos for ODBC, XLA, OCI, Pro*C/C++, and ODP.NET in subdirectories under the quickstart/sample_code directory. For instructions on compiling and running the demos, see the README files in the subdirectories.

- What the demos do: A synopsis of each demo is provided when you click the categories under SAMPLE PROGRAMS.

2

Working with TimesTen Databases in ODBC

This chapter covers TimesTen programming features and describes how to use ODBC to connect to and use the TimesTen database. It includes the following topics:

- Managing TimesTen database connections
- Managing TimesTen data
- Using additional TimesTen data management features
- Considering TimesTen features for access control
- Handling Errors
- Using automatic client failover in your application

Note that TimesTen supports ODBC 2.5, Extension Level 1, with additional features for Extension Level 2 where those features are included in Chapter 10, "TimesTen ODBC Functions and Options".

Notes:

- For using OCI to access TimesTen from a C application, see Chapter 3, "TimesTen Support for OCI".

- For using Pro*C/C++ to access TimesTen from a C application, see Chapter 4, "TimesTen Support for Pro*C/C++".

- For accessing TimesTen from a C++ application, see *Oracle TimesTen In-Memory Database TTClasses Guide*.

- For accessing TimesTen from a C# application, see *Oracle Data Provider for .NET Oracle TimesTen In-Memory Database Support User's Guide*.

Managing TimesTen database connections

The *Oracle TimesTen In-Memory Database Operations Guide* contains information about creating a DSN for the database. The type of DSN you create depends on whether your application will connect directly to the database or will connect by a client.

If you intend to connect directly to the database, refer to "Managing TimesTen Databases" in *Oracle TimesTen In-Memory Database Operations Guide*. There are sections on creating a DSN for a direct connection from UNIX or Windows.

If you intend to create a client connection to the database, refer to "Working with the TimesTen Client and Server" in *Oracle TimesTen In-Memory Database Operations Guide*.

There are sections on creating a DSN for a client/server connection from UNIX or Windows.

Notes:

- In TimesTen, the user name and password must be for a valid user who has been granted `CREATE SESSION` privilege to connect to the database.

- A TimesTen connection cannot be inherited from a parent process. If a process opens a database connection before creating (forking) a child process, the child must not use the connection.

The rest of this section covers the following topics:

- SQLConnect, SQLDriverConnect, SQLAllocConnect, SQLDisconnect functions
- Connecting to and disconnecting from a database
- Setting connection attributes programmatically
- Access control for connections

SQLConnect, SQLDriverConnect, SQLAllocConnect, SQLDisconnect functions

The following ODBC functions are available for connecting to a database and related functionality:

- `SQLConnect`: Loads a driver and connects to the database. The connection handle points to where information about the connection is stored, including status, transaction state, results, and error information.

- `SQLDriverConnect`: This is an alternative to `SQLConnect` when more information is required than what is supported by `SQLConnect`, which is just data source (the database), user name, and password.

- `SQLAllocConnect`: Allocates memory for a connection handle within the specified environment.

- `SQLDisconnect`: Disconnect from the database. Takes the existing connection handle as its only argument.

Refer to ODBC API reference documentation for additional details about these functions.

Connecting to and disconnecting from a database

This section provides examples of connecting to and disconnecting from the database.

Example 2–1   Connect and disconnect (excerpt)

This code fragment invokes `SQLConnect` and `SQLDisconnect` to connect to and disconnect from the database named `FixedDs`. The first invocation of `SQLConnect` by any application causes the creation of the `FixedDs` database. Subsequent invocations of `SQLConnect` would connect to the existing database.

```
#include <sql.h>
SQLRETURN retcode;
SQLHDBC hdbc;

...
```

```
retcode = SQLConnect(hdbc,
                     (SQLCHAR*)"FixedDs", SQL_NTS,
                     (SQLCHAR*)"johndoe", SQL_NTS,
                     (SQLCHAR*)"opensesame", SQL_NTS);
...
retcode = SQLDisconnect(hdbc);
...
```

Example 2–2   Connect and disconnect (complete program)

This example contains a complete program that creates, connects to, and disconnects from a database. The example uses SQLDriverConnect instead of SQLConnect to set up the connection, and uses SQLAllocConnect to allocate memory. It also shows how to get error messages. (In addition, you can refer to "Handling Errors" on page 2-34.)

```c
#ifdef WIN32
#include <windows.h>
#else
#include <sqlunix.h>
#endif
#include <sql.h>
#include <sqlext.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

static void chkReturnCode(SQLRETURN rc, SQLHENV henv,
                          SQLHDBC hdbc, SQLHSTMT hstmt,
                          char* msg, char* filename,
                          int lineno, BOOL err_is_fatal);
#define DEFAULT_CONNSTR "DSN=sampledb_1122;PermSize=32"

              switch (ret) {
                case SQL_SUCCESS:
                    fprintf(stderr, "*** %s\n"
                                "*** ODBC Error/Warning = %s, "
                                "TimesTen Error/Warning "
                                " = %d\n",
                                errMsg, sqlState,
                                nativeErr);
                break;
              case SQL_SUCCESS_WITH_INFO:
                fprintf(stderr, "*** Call to SQLError"
                        " failed with return code of "
                        "SQL_SUCCESS_WITH_INFO.\n "
                        "*** Need to increase size of"
                        " message buffer.\n");
                break;
              case SQL_INVALID_HANDLE:
                fprintf(stderr, "*** Call to SQLError"
                        " failed with return code of "
                        "SQL_INVALID_HANDLE.\n");
                break;
              case SQL_ERROR:
                fprintf(stderr, "*** Call to SQLError"
                        " failed with return code of "
                        "SQL_ERROR.\n");
                break;
              case SQL_NO_DATA_FOUND:
                break;
               } /* switch */
            } /* while */
            if (rc != SQL_SUCCESS_WITH_INFO && err_is_fatal) {
              fprintf(stderr, "Exiting.\n");
              exit(-1);
            }
        }
    }
```

Setting connection attributes programmatically

You can set or override connection attributes programmatically by specifying a connection string when you connect to a database.

Refer to *Oracle TimesTen In-Memory Database Operations Guide* for general information about connection attributes. General connection attributes require no special privilege. First connection attributes are set when the database is first loaded, and persist for all connections. Only the instance administrator can load a database with changes to first connection attribute settings. Refer to "Connection Attributes" in *Oracle TimesTen In-Memory Database Reference* for additional information, including specific information about any particular connection attribute.

Example 2–3   Connect and use store-level locking

This code fragment connects to a database named `mydsn` and indicates in the `SQLDriverConnect` call that the application should use a passthrough setting of 3. Note that `PassThrough` is a general connection attribute.

```
SQLHDBC hdbc;
SQLCHAR ConnStrOut[512];
SQLSMALLINT cbConnStrOut;
SQLRETURN rc;

rc = SQLDriverConnect(hdbc, NULL,
    "DSN=mydsn;PassThrough=3", SQL_NTS,
    ConnStrOut, sizeof (ConnStrOut),
    &cbConnStrOut, SQL_DRIVER_NOPROMPT);
```

> **Note:** Each connection to a database opens several files. An application with many threads, each with a separate connection, has several files open for each thread. Such an application can exceed the maximum allowed (or configured maximum) number of file descriptors that may be simultaneously open on the operating system. In this case, configure your system to allow a larger number of open files. See "Limits on number of open files" in *Oracle TimesTen In-Memory Database Reference*.

Access control for connections

In order for any user (other than the instance administrator) to connect to a database, the `CREATE SESSION` privilege must be granted. This is a system privilege so must be granted to the user by the instance administrator or someone with `ADMIN` privilege, either directly or through the `PUBLIC` role. Refer to "Managing Access Control" in *Oracle TimesTen In-Memory Database Operations Guide* for additional information and examples.

To create an XLA connection and execute XLA functionality, a user must be granted the `XLA` privilege, discussed in "Access control impact on XLA" on page 5-8, in addition to the `CREATE SESSION` privilege.

Managing TimesTen data

This section provides detailed information on working with data in a TimesTen database. It includes the following topics.

- TimesTen include files

- SQL statement execution within C applications
- Preparing and executing queries and working with cursors
- TimesTen deferred prepare
- Prefetching multiple rows of data
- Binding parameters and executing statements
- Working with REF CURSORs
- Working with DML returning (RETURNING INTO clause)
- Working with rowids
- Working with LOBs
- Making and committing changes to the database

TimesTen include files

In addition to standard C "include" files, your application must include the TimesTen files shown in the following table.

Include file	Description
timesten.h	TimesTen ODBC include file
tt_errCode.h	TimesTen native error codes

SQL statement execution within C applications

"Working with Data in a TimesTen Database" in *Oracle TimesTen In-Memory Database Operations Guide* describes how to use SQL to manage data. This section describes general formats used to execute a SQL statement within a C application. The following topics are covered:

- SQLExecDirect and SQLExecute functions
- Executing a SQL statement

> **Note:** Access control privileges are checked both when SQL is prepared and when it is executed in the database. Refer to "Considering TimesTen features for access control" on page 2-33 for related information.

SQLExecDirect and SQLExecute functions

There are two ODBC functions to execute SQL statements:

- SQLExecute: Executes a statement that has been prepared with SQLPrepare. After the application is done with the results, they can be discarded and SQLExecute can be run again using different parameter values.

    This is typically used for DML statements with bind parameters, or statements that are being executed more than once.

- SQLExecDirect: Prepares and executes a statement.

    This is typically used for DDL statements or for DML statements that would execute only a few times and without bind parameters.

Refer to ODBC API reference documentation for details about these functions.

Executing a SQL statement

You can use the SQLExecDirect function as shown in Example 2–4.

The next section, "Preparing and executing queries and working with cursors", shows usage of the SQLExecute and SQLPrepare functions.

Example 2–4   Executing a SQL statement with SQLExecDirect

This code sample creates a table, NameID, with two columns: CustID and CustName. The table maps character names to integer identifiers.

```
#include <sql.h>
SQLRETURN rc;
SQLHSTMT hstmt;
...
rc = SQLExecDirect(hstmt, (SQLCHAR*)
     "CREATE TABLE NameID (CustID INTEGER, CustName VARCHAR(50))",
     SQL_NTS);
if (rc != SQL_SUCCESS && rc != SQL_SUCCESS_WITH_INFO)
     ... /* handle error */
```

Preparing and executing queries and working with cursors

This section shows the basic steps of preparing and executing a query and working with cursors. Applications use cursors to scroll through the results of a query, examining one result row at a time.

> **Important:**   In TimesTen, any operation that ends your transaction, such as a commit or rollback, closes all cursors associated with the connection.

In the ODBC setting, a cursor is always associated with a result set. This association is made by the ODBC driver. The application can control cursor characteristics, such as the number of rows to fetch at one time, using SQLSetStmtOption options documented in "Option support for SQLSetStmtOption and SQLGetStmtOption" on page 10-5. The steps involved in executing a query typically include the following.

1. Use SQLPrepare to prepare the SELECT statement for execution.

2. Use SQLBindParameter, if the statement has parameters, to bind each parameter to an application address. See "SQLBindParameter function" on page 2-12. (Note that Example 2–5 below does not bind parameters.)

3. Call SQLBindCol to assign the storage and data type for a column of results, binding column results to local variable storage in your application.

4. Call SQLExecute to execute the SELECT statement. See "SQLExecDirect and SQLExecute functions" on page 2-7.

5. Call SQLFetch to fetch the results. Specify the statement handle.

6. Call SQLFreeStmt to free the statement handle. Specify the statement handle and either SQL_CLOSE, SQL_DROP, SQL_UNBIND, or SQL_RESET_PARAMS.

Refer to ODBC API reference documentation for details on these ODBC functions. Examples are shown throughout this chapter and in the TimesTen Quick Start (through the "ODBC (C)" link under SAMPLE PROGRAMS).

> **Notes:**
>
> - Access control privileges are checked both when SQL is prepared and when it is executed in the database. Refer to "Considering TimesTen features for access control" on page 2-33 for related information.
>
> - By default (when connection attribute `PrivateCommands=0`), TimesTen shares prepared statements between connections, so subsequent prepares of the same statement on different connections execute very quickly.

Example 2–5   Executing a query and working with the cursor

This example illustrates how to prepare and execute a query using ODBC calls. Error checking has been omitted to simplify the example. In addition to ODBC functions mentioned previously, this example uses `SQLNumResultCols` to return the number of columns in the result set, `SQLDescribeCol` to return a description of one column of the result set (column name, type, precision, scale, and nullability), and `SQLBindCol` to assign the storage and data type for a column in the result set. These are all described in detail in ODBC API reference documentation.

```
#include <sql.h>

SQLHSTMT hstmt;
SQLRETURN rc;
int i;
SQLSMALLINT numCols;
SQLCHAR colname[32];
SQLSMALLINT colnamelen, coltype, scale, nullable;
SQLULEN collen [MAXCOLS];
SQLLEN outlen [MAXCOLS];
SQLCHAR* data [MAXCOLS];

/* other declarations and program set-up here */

/* Prepare the SELECT statement */
rc = SQLPrepare(hstmt,
(SQLCHAR*) "SELECT * FROM EMP WHERE AGE>20",
SQL_NTS);
/* ... */

/* Determine number of columns in result rows */
rc = SQLNumResultCols(hstmt, &numCols);

/* ... */

/* Describe and bind the columns */
for (i = 0; i < numCols; i++) {
    rc = SQLDescribeCol(hstmt,
        (SQLSMALLINT) (i + 1),
        colname,(SQLSMALLINT)sizeof(colname), &colnamelen, &coltype, &collen[i],
        &scale, &nullable);

    /* ... */

    data[i] = (SQLCHAR*) malloc (collen[i] +1);  //Allocate space for column data.
    rc = SQLBindCol(hstmt, (SQLSMALLINT) (i + 1),
```

```
                          SQL_C_CHAR, data[i],
                          COL_LEN_MAX, &outlen[i]);

    /* ... */

}
/* Execute the SELECT statement */
rc = SQLExecute(hstmt);

/* ... */

/* Fetch the rows */
if (numCols > 0) {
  while ((rc = SQLFetch(hstmt)) == SQL_SUCCESS ||
         rc == SQL_SUCCESS_WITH_INFO) {
    /* ... "Process" the result row */
  } /* end of for-loop */
  if (rc != SQL_NO_DATA_FOUND)
    fprintf(stderr,
            "Unable to fetch the next row\n");

/* Close the cursor associated with the SELECT statement */
  rc = SQLFreeStmt(hstmt, SQL_CLOSE);
}
```

TimesTen deferred prepare

In standard ODBC, a `SQLPrepare` call compiles a SQL statement so that information about the statement, such as column descriptions for the result set, is available to the application and accessible through calls such as `SQLDescribeCol`. To accomplish this, the `SQLPrepare` call must communicate with the server for processing.

This is in contrast, for example, to expected behavior under Oracle Call Interface (OCI), where a prepare call is expected to be a lightweight operation performed on the client to simply extract names and positions of parameters.

To avoid unwanted round trips between client and server, and also to make the behavior consistent with OCI expectations, the TimesTen client library implementation of `SQLPrepare` performs what is referred to as a "deferred prepare", where the request is not sent to the server until required. Examples of when the round trip would be required:

- When there is a `SQLExecute` call. Note that if there is a deferred prepare call that has not yet been sent to the server, a `SQLExecute` call on the client is converted to a `SQLExecDirect` call.

- When there is a request for information about the query that can only be supplied by the SQL engine, such as when there is a `SQLDescribeCol` call, for example. Many such calls in standard ODBC can access information previously returned by a `SQLPrepare` call, but with the deferred prepare functionality the `SQLPrepare` call is sent to the server and the information is returned to the application only as needed.

> **Note:** Deferred prepare functionality is not implemented (and not necessary) with the TimesTen direct driver.

The deferred prepare implementation requires no changes at the application or user level; however, be aware that calling any of the following functions may result in a

round trip to the server if the required information from a previously prepared statement has not yet been retrieved:

- `SQLColAttributes`

- `SQLDescribeCol`

- `SQLDescribeParam`

- `SQLNumResultCols`

- `SQLNumParams`

- `SQLGetStmtOption` (for options that depend on the statement having been compiled by the SQL engine)

Also be aware that when calling any of these functions, any error from an earlier `SQLPrepare` call may be deferred until one of these calls is executed. In addition, these calls may return errors specific to `SQLPrepare` as well as errors specific to themselves.

Prefetching multiple rows of data

A TimesTen extension to ODBC enables applications to prefetch multiple rows of data into the ODBC driver buffer. This can improve performance of client/server applications.

The `TT_PREFETCH_COUNT` connection option determines how many rows a `SQLFetch` call will prefetch. Note that this option provides no benefit for an application using a direct connection to TimesTen.

`TT_PREFETCH_COUNT` can be set in a call to either `SQLSetConnectOption` or `SQLSetStmtOption`. The value can be any integer from 0 to 128, inclusive. Following is an example.

```
rc = SQLSetConnectOption(hdbc, TT_PREFETCH_COUNT, 100);
```

With this setting, the first `SQLFetch` call on the connection will prefetch 100 rows. Subsequent `SQLFetch` calls will fetch from the ODBC buffer instead of from the database, until the buffer is depleted. After it is depleted, the next `SQLFetch` call will fetch another 100 rows into the buffer, and so on.

To disable prefetch, set `TT_PREFETCH_COUNT` to 1.

When the prefetch count is set to 0, TimesTen uses a default value, depending on the isolation level you have set for the database. With Read Committed isolation level, the default prefetch value is 5. With Serializable isolation level, the default is 128. The default prefetch value is a good setting for most applications. Generally, a higher value may result in better performance for larger result sets, at the expense of slightly higher resource use.

Binding parameters and executing statements

This section discusses how to bind input or output parameters for SQL statements. The following topics are covered:

- SQLBindParameter function

- Determination of parameter type assignments and type conversions

- Binding input parameters

- Binding output parameters

- Binding input/output parameters

- [Binding duplicate parameters in SQL statements](#)
- [Binding duplicate parameters in PL/SQL](#)
- [Considerations for floating point data](#)
- [Using SQL_WCHAR and SQL_WVARCHAR with a driver manager](#)

> **Note:** The term "bind parameter" as used in TimesTen developer guides (in keeping with ODBC terminology) is equivalent to the term "bind variable" as used in TimesTen PL/SQL documents (in keeping with Oracle PL/SQL terminology).

SQLBindParameter function

The ODBC `SQLBindParameter` function is used to bind parameters for SQL statements. This could include input, output, or input/output parameters.

To bind an input parameter through ODBC, use the `SQLBindParameter` function with a setting of `SQL_PARAM_INPUT` for the *fParamType* argument. Refer to ODBC API reference documentation for details about the `SQLBindParameter` function. Table 2–1 provides a brief summary of its arguments.

To bind an output or input/output parameter through ODBC, use the `SQLBindParameter` function with a setting of `SQL_PARAM_OUTPUT` or `SQL_PARAM_INPUT_OUTPUT`, respectively, for the *fParamType* argument. As with input parameters, use the *fSqlType*, *cbColDef*, and *ibScale* arguments (as applicable) to specify data types.

Table 2–1   SQLBindParameter arguments

Argument	Type	Description
hstmt	SQLHSTMT	Statement handle
ipar	SQLUSMALLINT	Parameter number, sequentially from left to right, starting with 1
fParamType	SQLSMALLINT	Indicating input or output: `SQL_PARAM_INPUT`, `SQL_PARAM_OUTPUT`, or `SQL_PARAM_INPUT_OUTPUT`
fCType	SQLSMALLINT	C data type of the parameter
fSqlType	SQLSMALLINT	SQL data type of the parameter
cbColDef	SQLULEN	The precision of the parameter, such as the maximum number of bytes for binary data, the maximum number of digits for a number, or the maximum number of characters for character data
ibScale	SQLSMALLINT	The scale of the parameter, referring to the maximum number of digits to the right of the decimal point, where applicable
rgbValue	SQLPOINTER	Pointer to a buffer for the data of the parameter
cbValueMax	SQLLEN	Maximum length of the *rgbValue* buffer, in bytes
pcbValue	SQLLEN*	Pointer to a buffer for the length of the parameter

> **Note:** Refer to "Data Types" in *Oracle TimesTen In-Memory Database SQL Reference* for information about precision and scale of TimesTen data types.

Determination of parameter type assignments and type conversions

Bind parameter type assignments are determined as follows.

- Parameter type assignments for statements that execute in TimesTen are determined by TimesTen. Specifically:

  - For SQL statements that execute within TimesTen, the TimesTen query optimizer determines data types of SQL parameters.

- Parameter type assignments for statements that execute in Oracle Database, or according to Oracle Database functionality, are determined by the application as follows.

  - For SQL statements that execute within Oracle Database—that is, passthrough statements from the Oracle In-Memory Database Cache (IMDB Cache)—the application must specify data types through its calls to the ODBC `SQLBindParameter` function, according to the *fSqlType*, *cbColDef*, and *ibScale* arguments of that function, as applicable.

  - For PL/SQL blocks or procedures that execute within TimesTen, where the PL/SQL execution engine has the same basic functionality as in Oracle Database, the application must specify data types through its calls to `SQLBindParameter` (the same as for SQL statements that execute within Oracle Database).

    So regarding host binds for PL/SQL (the variables, or parameters, that are preceded by a colon within a PL/SQL block), note that the type of a host bind is effectively declared by the call to `SQLBindParameter`, according to *fSqlType* and the other arguments as applicable, and is not declared within the PL/SQL block.

The ODBC driver performs any necessary type conversions between C values and SQL or PL/SQL types. For any C-to-SQL or C-to-PL/SQL combination that is not supported, an error will occur. These conversions can be from a C type to a SQL or PL/SQL type (input parameter), from a SQL or PL/SQL type to a C type (output parameter), or both (input/output parameter).

Table 2–2 documents the mapping between ODBC types and SQL or PL/SQL types.

Table 2–2   ODBC SQL to TimesTen SQL or PL/SQL type mappings

ODBC type (*fSqlType*)	SQL or PL/SQL type
SQL_BIGINT	NUMBER
SQL_BINARY	RAW(*p*)
SQL_BIT	PLS_INTEGER
SQL_CHAR	CHAR(*p*)
SQL_DATE	DATE
SQL_DECIMAL	NUMBER
SQL_DOUBLE	NUMBER
SQL_FLOAT	BINARY_DOUBLE
SQL_INTEGER	PLS_INTEGER
SQL_NUMERIC	NUMBER
SQL_REAL	BINARY_FLOAT
SQL_REFCURSOR	REF CURSOR

Table 2–2 (Cont.) ODBC SQL to TimesTen SQL or PL/SQL type mappings

ODBC type (*fSqlType*)	SQL or PL/SQL type
SQL_ROWID	ROWID
SQL_SMALLINT	PLS_INTEGER
SQL_TIMESTAMP	TIMESTAMP(*s*)
SQL_TINYINT	PLS_INTEGER
SQL_VARBINARY	RAW(*p*)
SQL_VARCHAR	VARCHAR2(*p*)
SQL_WCHAR	NCHAR(*p*)
SQL_WVARCHAR	NVARCHAR2(*p*)

Notes:

- The notation (*p*) indicates precision is according to the SQLBindParameter argument *cbColDef*.

- The notation (*s*) indicates scale is according to the SQLBindParameter argument *ibScale*.

- Most applications should use SQL_VARCHAR rather than SQL_CHAR for binding character data. Use of SQL_CHAR may result in unwanted space padding to the full precision of the parameter type.

Binding input parameters

For input parameters to PL/SQL in TimesTen, use the *fSqlType*, *cbColDef*, and *ibScale* arguments (as applicable) of the ODBC SQLBindParameter function to specify data types. This is in contrast to how SQL input parameters are supported, as noted in the preceding section, "Determination of parameter type assignments and type conversions".

In addition, the *rgbValue*, *cbValueMax*, and *pcbValue* arguments of SQLBindParameter are used as follows for input parameters:

- *rgbValue*: Before statement execution, points to the buffer where the application places the parameter value to be passed to the application.

- *cbValueMax*: For character and binary data, indicates the maximum length of the incoming value that *rgbValue* points to, in bytes. For all other data types, *cbValueMax* is ignored, and the length of the value that *rgbValue* points to is determined by the length of the C data type specified in the *fCType* argument of SQLBindParameter.

- *pcbValue*: Points to a buffer that contains one of the following before statement execution:

  – The actual length of the value that *rgbValue* points to

    Note: For input parameters, this would be valid only for character or binary data.

  – SQL_NTS for a null-terminated string

  – SQL_NULL_DATA for a null value

Binding output parameters

For output parameters from PL/SQL in TimesTen, as noted for input parameters previously, use the *fSqlType*, *cbColDef*, and *ibScale* arguments (as applicable) of the ODBC SQLBindParameter function to specify data types.

In addition, the *rgbValue*, *cbValueMax*, and *pcbValue* arguments of SQLBindParameter are used as follows for output parameters:

■ *rgbValue*: During statement execution, points to the buffer where the value returned from the statement should be placed.

■ *cbValueMax*: For character and binary data, indicates the maximum length of the outgoing value that *rgbValue* points to, in bytes. For all other data types, *cbValueMax* is ignored, and the length of the value that *rgbValue* points to is determined by the length of the C data type specified in the *fCType* argument of SQLBindParameter.

   Note that ODBC null-terminates all character data, even if the data is truncated. Therefore, when an output parameter has character data, *cbValueMax* must be large enough to accept the maximum data value plus a null terminator (one additional byte for CHAR and VARCHAR parameters, or two additional bytes for NCHAR and NVARCHAR parameters).

■ *pcbValue*: Points to a buffer that contains one of the following after statement execution:

   – The actual length of the value that *rgbValue* points to (for all C types, not just character and binary data)

      Note: This is the length of the full parameter value, regardless of whether the value can fit in the buffer that *rgbValue* points to.

   – SQL_NULL_DATA for a null value

Example 2–6   Binding output parameters

This example shows how to prepare, bind, and execute a PL/SQL anonymous block. The anonymous block assigns bind parameter a the value 'abcde' and bind parameter b the value 123.

SQLPrepare prepares the anonymous block. SQLBindParameter binds the first parameter (a) as an output parameter of type SQL_VARCHAR and binds the second parameter (b) as an output parameter of type SQL_INTEGER. SQLExecute executes the anonymous block.

```
{
  SQLHSTMT      hstmt;
  char          aval[11];
  SQLLEN        aval_len;
  SQLINTEGER    bval;
  SQLLEN        bval_len;

  SQLAllocStmt(hdbc, &hstmt);

  SQLPrepare(hstmt,
        (SQLCHAR*)"begin :a := 'abcde'; :b := 123; end;",
        SQL_NTS);

  SQLBindParameter(hstmt, 1, SQL_PARAM_OUTPUT, SQL_C_CHAR, SQL_VARCHAR,
        10, 0, (SQLPOINTER)aval, sizeof(aval), &aval_len);

  SQLBindParameter(hstmt, 2, SQL_PARAM_OUTPUT, SQL_C_SLONG, SQL_INTEGER,
```

```
                    0, 0, (SQLPOINTER)&bval, sizeof(bval), &bval_len);

   SQLExecute(hstmt);
   printf("aval = [%s] (length = %d), bval = %d\n", aval, (int)aval_len, bval);
}
```

Binding input/output parameters

For input/output parameters to and from PL/SQL in TimesTen, as noted for input parameters previously, use the *fSqlType*, *cbColDef*, and *ibScale* arguments (as applicable) of the ODBC SQLBindParameter function to specify data types.

In addition, the *rgbValue*, *cbValueMax*, and *pcbValue* arguments of SQLBindParameter are used as follows for input/output parameters:

- *rgbValue*: This is first used before statement execution as described in "Binding input parameters" on page 2-14. Then it is used during statement execution as described in the preceding section, "Binding output parameters". Note that for an input/output parameter, the outgoing value from a statement execution will be the incoming value to the statement execution that immediately follows, unless that is overridden by the application. Also, for input/output values bound when you are using data-at-execution, the value of *rgbValue* serves as both the token that would be returned by the ODBC SQLParamData function and as the pointer to the buffer where the outgoing value will be placed.

- *cbValueMax*: For character and binary data, this is first used as described in "Binding input parameters" on page 2-14. Then it is used as described in the preceding section, "Binding output parameters". For all other data types, *cbValueMax* is ignored, and the length of the value that *rgbValue* points to is determined by the length of the C data type specified in the *fCType* argument of SQLBindParameter.

  Note that ODBC null-terminates all character data, even if the data is truncated. Therefore, when an input/output parameter has character data, *cbValueMax* must be large enough to accept the maximum data value plus a null terminator (one additional byte for CHAR and VARCHAR parameters, or two additional bytes for NCHAR and NVARCHAR parameters).

- *pcbValue*: This is first used before statement execution as described in "Binding input parameters" on page 2-14. Then it is used after statement execution as described in the preceding section, "Binding output parameters".

> **Important:** For character and binary data, carefully consider the value you use for *cbValueMax*. A value that is smaller than the actual buffer size may result in spurious truncation warnings. A value that is greater than the actual buffer size may cause the ODBC driver to overwrite the *rgbValue* buffer, resulting in memory corruption.

Binding duplicate parameters in SQL statements

TimesTen supports two distinct modes for binding duplicate parameters in a SQL statement. (Regarding PL/SQL statements, see "Binding duplicate parameters in PL/SQL" on page 2-18.)

- Oracle mode, where multiple occurrences of the same parameter name are considered to be distinct parameters

- Traditional TimesTen mode, as in earlier releases, where multiple occurrences of the same parameter name are considered to be the same parameter

You can choose the desired mode through the `DuplicateBindMode` TimesTen general connection attribute. `DuplicateBindMode=0` (the default) is for the Oracle mode, and `DuplicateBindMode=1` is for the TimesTen mode. Because this is a general connection attribute, different connections to the same database can use different values. Refer to "DuplicateBindMode" in *Oracle TimesTen In-Memory Database Reference* for additional information about this attribute.

The rest of this section provides details for each mode, considering the following query:

```
SELECT * FROM employees
  WHERE employee_id < :a AND manager_id > :a AND salary < :b;
```

Notes:

- This discussion applies only to SQL statements issued directly from ODBC (not through PL/SQL, for example).

- The use of "`?`" for parameters, not supported in Oracle Database, is supported by TimesTen in either mode.

Oracle mode for duplicate parameters In Oracle mode, where `DuplicateBindMode=0`, multiple occurrences of the same parameter name in a SQL statement are considered to be different parameters. When parameter position numbers are assigned, a number is given to each parameter occurrence without regard to name duplication. The application must, at a minimum, bind a value for the first occurrence of each parameter name. For any subsequent occurrence of a given parameter name, the application has the following choices.

- It can bind a different value for the occurrence.

- It can leave the parameter occurrence unbound, in which case it takes the same value as the first occurrence.

In either case, each occurrence still has a distinct parameter position number.

To use a different value for the second occurrence of `a` in the SQL statement above:

```
SQLBindParameter(..., 1, ...); /* first occurrence of :a */
SQLBindParameter(..., 2, ...); /* second occurrence of :a */
SQLBindParameter(..., 3, ...); /* occurrence of :b */
```

To use the same value for both occurrences of `a`:

```
SQLBindParameter(..., 1, ...); /* both occurrences of :a */
SQLBindParameter(..., 3, ...); /* occurrence of :b */
```

Parameter `b` is considered to be in position 3 regardless.

In Oracle mode, the `SQLNumParams` ODBC function returns 3 for the number of parameters in the example.

TimesTen mode for duplicate parameters In TimesTen mode, where `DuplicateBindMode=1`, SQL statements containing duplicate parameters are parsed such that only distinct parameter names are considered as separate parameters.

Binding is based on the position of the first occurrence of a parameter name. Subsequent occurrences of the parameter name are not given their own position numbers. All occurrences of the same parameter name take on the same value.

For the SQL statement above, the two occurrences of a are considered to be a single parameter, so cannot be bound separately:

```
SQLBindParameter(..., 1, ...); /* both occurrences of :a */
SQLBindParameter(..., 2, ...); /* occurrence of :b */
```

Note that in TimesTen mode, parameter b is considered to be in position 2, not position 3.

In TimesTen mode, the SQLNumParams ODBC function returns 2 for the number of parameters in the example.

Binding duplicate parameters in PL/SQL

The preceding discussion does not apply to PL/SQL, which has its own semantics. In PL/SQL, you bind a value for each unique parameter name. An application executing the following block, for example, would bind only one parameter, corresponding to :a.

```
DECLARE
    x NUMBER;
    y NUMBER;
BEGIN
    x:=:a;
    y:=:a;
END;
```

An application executing the following block would also bind only one parameter:

```
BEGIN
    INSERT INTO tab1 VALUES(:a, :a);
END
```

And the same for the following CALL statement:

```
...CALL proc(:a, :a)...
```

An application executing the following block would bind two parameters, with :a as the first parameter and :b as the second parameter. The second parameter in each INSERT statement would take the same value as the first parameter in the first INSERT statement:

```
BEGIN
    INSERT INTO tab1 VALUES(:a, :a);
    INSERT INTO tab1 VALUES(:b, :a);
END
```

Considerations for floating point data

The BINARY_DOUBLE and BINARY_FLOAT data types store and retrieve the IEEE floating point values Inf, -Inf, and NaN. If an application uses a C language facility such as printf, scanf, or strtod that requires conversion to character data, the floating point values are returned as "INF", "-INF", and "NAN". These character strings cannot be converted back to floating point values.

Using SQL_WCHAR and SQL_WVARCHAR with a driver manager

Applications using the Windows driver manager may encounter errors from SQLBindParameter with SQL state S1004 (SQL data type out of range) when passing an *fSqlType* value of SQL_WCHAR or SQL_WVARCHAR. This problem can be avoided by passing one of the following values for *fSqlType* instead.

- SQL_WCHAR_DM_SQLBINDPARAMETER_BYPASS instead of SQL_WCHAR

- SQL_WVARCHAR_DM_SQLBINDPARAMETER_BYPASS instead of SQL_WVARCHAR

These type codes are semantically identical to SQL_WCHAR and SQL_WVARCHAR but avoid the error from the Windows driver manager. They can be used in applications that link with the driver manager or link directly with the TimesTen ODBC direct driver or ODBC client driver.

See "SQLBindParameter function" on page 2-12 for information about that ODBC function.

Working with REF CURSORs

REF CURSOR is a PL/SQL concept, a handle to a cursor over a SQL result set that can be passed between PL/SQL and an application. In TimesTen, the cursor can be opened in PL/SQL then the REF CURSOR can be passed to the application. The results can be processed in the application using ODBC calls. This is an OUT REF CURSOR (an OUT parameter with respect to PL/SQL). The REF CURSOR is attached to a statement handle, enabling applications to describe and fetch result sets using the same APIs as for any result set.

Take the following steps to use a REF CURSOR. Assume a PL/SQL statement that returns a cursor through a REF CURSOR OUT parameter. Note that REF CURSORs use the same basic steps of prepare, bind, execute, and fetch as in the cursor example in "Preparing and executing queries and working with cursors" on page 2-8.

1. Prepare the PL/SQL statement, using SQLPrepare, to be associated with the first statement handle.

2. Bind each parameter of the statement, using SQLBindParameter. When binding the REF CURSOR output parameter, use an allocated second statement handle as *rgbValue*, the pointer to the data buffer.

   The *pcbValue*, *ibScale*, *cbValueMax*, and *pcbValue* arguments are ignored for REF CURSORs.

   See "SQLBindParameter function" on page 2-12 and "Binding output parameters" on page 2-15 for information about these and other SQLBindParameter arguments.

3. Call SQLBindCol to bind result columns to local variable storage.

4. Call SQLExecute to execute the statement.

5. Call SQLFetch to fetch the results. After a REF CURSOR is passed from PL/SQL to an application, the application can describe and fetch the results as it would for any result set.

6. Use SQLFreeStmt to free the statement handle.

These steps are demonstrated in the example that follows. Refer to ODBC API reference documentation for details on these functions. See "PL/SQL REF CURSORs" in *Oracle TimesTen In-Memory Database PL/SQL Developer's Guide* for additional information about REF CURSORs.

> **Important:** For passing REF CURSORs between PL/SQL and an application, TimesTen supports only OUT REF CURSORs, from PL/SQL to the application, and supports a statement returning only a single REF CURSOR.

Example 2–7   Executing a query and working with a REF CURSOR

This example, using a REF CURSOR in a loop, demonstrates the basic steps of preparing a query, binding parameters, executing the query, binding results to local variable storage, and fetching the results. Error handling is omitted for simplicity. In addition to the ODBC functions summarized earlier, this example uses SQLAllocStmt to allocate memory for a statement handle.

```
refcursor_example(SQLHDBC hdbc)
{
  SQLCHAR*      stmt_text;
  SQLHSTMT      plsql_hstmt;
  SQLHSTMT      refcursor_hstmt;
  SQLINTEGER    deptid;
  SQLINTEGER    depts[3] = {10,30,40};
  SQLINTEGER    empid;
  SQLCHAR       lastname[30];
  SQLINTEGER    i;

  /* allocate 2 statement handles: one for the plsql statement and
   * one for the ref cursor */
  SQLAllocStmt(hdbc, &plsql_hstmt);
  SQLAllocStmt(hdbc, &refcursor_hstmt);

  /* prepare the plsql statement */
  stmt_text = (SQLCHAR*)
    "begin "
      "open :refc for "
        "select employee_id, last_name "
        "from employees "
        "where department_id = :dept; "
    "end;";
  SQLPrepare(plsql_hstmt, stmt_text, SQL_NTS);

  /* bind parameter 1 (:refc) to refcursor_hstmt */
  SQLBindParameter(plsql_hstmt, 1, SQL_PARAM_OUTPUT, SQL_C_REFCURSOR,
                   SQL_REFCURSOR, 0, 0, refcursor_hstmt, 0, 0);

  /* bind parameter 2 (:deptid) to local variable deptid */
  SQLBindParameter(plsql_hstmt, 2, SQL_PARAM_INPUT, SQL_C_SLONG,
                   SQL_INTEGER, 0, 0, &deptid, 0, 0);

  /* loop through values for :deptid */
  for (i=0; i<3; i++)
  {
     deptid = depts[i];

     /* execute the plsql statement */
     SQLExecute(plsql_hstmt);
     /*
      * The result set is now attached to refcursor_hstmt.
      * Bind the result columns and fetch the result set.
      */

     /* bind result column 1 to local variable empid */
     SQLBindCol(refcursor_hstmt, 1, SQL_C_SLONG,
                (SQLPOINTER)&empid, 0, 0);

     /* bind result column 2 to local variable lastname */
     SQLBindCol(refcursor_hstmt, 2, SQL_C_CHAR,
                (SQLPOINTER)lastname, sizeof(lastname), 0);
```

```
       /* fetch the result set */
       while(SQLFetch(refcursor_hstmt) != SQL_NO_DATA_FOUND){
         printf("%d, %s\n", empid, lastname);
       }

       /* close the ref cursor statement handle */
       SQLFreeStmt(refcursor_hstmt, SQL_CLOSE);
   }

   /* drop both handles */
   SQLFreeStmt(plsql_hstmt, SQL_DROP);
   SQLFreeStmt(refcursor_hstmt, SQL_DROP);
}
```

Working with DML returning (RETURNING INTO clause)

You can use a RETURNING INTO clause, referred to as *DML returning*, with an INSERT, UPDATE, or DELETE statement to return specified items from a row that was affected by the action. This eliminates the need for a subsequent SELECT statement and separate round trip in case, for example, you want to confirm what was affected by the action.

With ODBC, DML returning is limited to returning items from a single-row operation. The clause returns the items into a list of output parameters. Bind the output parameters as discussed in "Binding parameters and executing statements" on page 2-11.

SQL syntax and restrictions for the RETURNING INTO clause in TimesTen are documented as part of "INSERT", "UPDATE", and "DELETE" in *Oracle TimesTen In-Memory Database SQL Reference*.

Refer to "RETURNING INTO Clause" in *Oracle Database PL/SQL Language Reference* for details about DML returning.

Example 2–8   DML returning

This example is adapted from Example 2–10 on page 2-27, with bold text highlighting key portions.

```
void
update_example(SQLHDBC hdbc)
{
   SQLCHAR*     stmt_text;
   SQLHSTMT     hstmt;
   SQLINTEGER   raise_pct;
   char         hiredate_str[30];
   char         last_name[30];
   SQLLEN       hiredate_len;
   SQLLEN       numrows;

   /* allocate a statement handle */
   SQLAllocStmt(hdbc, &hstmt);

   /* prepare an update statement to give a raise to one employee hired
      before a given date and return that employee's last name */
   stmt_text = (SQLCHAR*)
     "update employees "
     "set salary = salary * ((100 + :raise_pct) / 100.0) "
     "where hire_date < :hiredate and rownum = 1 returning last_name into "
                     ":last_name";
   SQLPrepare(hstmt, stmt_text, SQL_NTS);
```

```
      /* bind parameter 1 (:raise_pct) to variable raise_pct */
      SQLBindParameter(hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                       SQL_DECIMAL, 0, 0, (SQLPOINTER)&raise_pct, 0, 0);

      /* bind parameter 2 (:hiredate) to variable hiredate_str */
      SQLBindParameter(hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                       SQL_TIMESTAMP, 0, 0, (SQLPOINTER)hiredate_str,
                       sizeof(hiredate_str), &hiredate_len);
      /* bind parameter 3 (:last_name) to variable last_name */
      SQLBindParameter(hstmt, 3, SQL_PARAM_OUTPUT, SQL_C_CHAR,
                       SQL_VARCHAR, 30, 0, (SQLPOINTER)last_name,
                       sizeof(last_name), NULL);
      /* set parameter values to give a 10% raise to an employee hired before
       * January 1, 1996. */
      raise_pct = 10;
      strcpy(hiredate_str, "1996-01-01");
      hiredate_len = SQL_NTS;

      /* execute the update statement */
      SQLExecute(hstmt);

      /* tell us who the lucky person is */
      printf("Gave raise to %s.\n", last_name );

      /* drop the statement handle */
      SQLFreeStmt(hstmt, SQL_DROP);

      /* commit the changes */
      SQLTransact(henv, hdbc, SQL_COMMIT);

}
```

This returns "King" as the recipient of the raise.

Working with rowids

Each row in a database table has a unique identifier known as its *rowid*. An application can retrieve the rowid of a row from the ROWID pseudocolumn. Rowids can be represented in either binary or character format.

An application can specify literal rowid values in SQL statements, such as in WHERE clauses, as CHAR constants enclosed in single quotes.

As noted in Table 2–2 on page 2-13, the ODBC SQL type SQL_ROWID corresponds to the SQL type ROWID.

For parameters and result set columns, rowids are convertible to and from the C types SQL_C_BINARY, SQL_C_WCHAR, and SQL_C_CHAR. SQL_C_CHAR is the default C type for rowids. The size of a rowid would be 12 bytes as SQL_C_BINARY, 18 bytes as SQL_C_CHAR, and 36 bytes as SQL_C_WCHAR.

Refer to "ROWID data type" and "ROWID" in *Oracle TimesTen In-Memory Database SQL Reference* for additional information about rowids and the ROWID data type, including usage and life.

> **Note:** TimesTen does not support the PL/SQL type UROWID.

Working with LOBs

TimesTen supports LOBs (large objects). This includes CLOBs (character LOBs), NCLOBs (national character LOBs), and BLOBs (binary LOBs).

This section provides a brief overview of LOBs and discusses their use in ODBC, covering the following topics:

- About LOBs
- Differences between TimesTen LOBs and Oracle Database LOBs
- LOB programming interfaces
- Using the LOB simple data interface in ODBC
- Using the LOB piecewise data interface in ODBC
- Passthrough LOBs in ODBC

> **Note:** TimesTen does not support CLOBs if the database character set is `TIMESTEN8`.

You can also refer to the following:

- "LOBs in TimesTen OCI" on page 3-19 and "LOBs in TimesTen Pro*C/C++" on page 4-10 for information specific to those APIs
- "LOB data types" in *Oracle TimesTen In-Memory Database SQL Reference* for additional information about LOBs in TimesTen
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for general information about programming with LOBs (but not specific to TimesTen functionality)

About LOBs

A LOB is a large binary object (BLOB) or character object (CLOB or NCLOB). In TimesTen, a BLOB can be up to 16 MB in size and a CLOB or NCLOB up to 4 MB. LOBs in TimesTen have essentially the same functionality as in Oracle Database, except as noted otherwise. (See the next section, "Differences between TimesTen LOBs and Oracle Database LOBs".)

LOBs may be either persistent or temporary. A persistent LOB exists in a LOB column in the database. A temporary LOB exists only within an application. There are circumstances where a temporary LOB is created implicitly by TimesTen. For example, if a `SELECT` statement selects a LOB concatenated with an additional string of characters, TimesTen will create a temporary LOB to contain the concatenated data. In TimesTen ODBC, any temporary LOBs are managed implicitly.

Temporary LOBs are stored in the TimesTen temporary data partition.

Differences between TimesTen LOBs and Oracle Database LOBs

Be aware of the following:

- A key difference between the TimesTen LOB implementation and the Oracle Database implementation is that in TimesTen, a LOB used in an application does not remain valid past the end of the transaction. All such LOBs are invalidated after a commit or rollback, whether explicit or implicit. This includes after any DDL statement if TimesTen `DDLCommitBehavior` is set to 0 (the default), for Oracle Database behavior.

- TimesTen does not support BFILEs, SecureFiles, array reads and writes for LOBs, or callback functions for LOBs.

- TimesTen does not support binding arrays of LOBs.

- TimesTen does not support batch processing of LOBs.

- Relevant to BLOBs, there are differences in the usage of hexadecimal literals in TimesTen. see the description of *HexadecimalLiteral* in "Constants" in *Oracle TimesTen In-Memory Database SQL Reference*.

LOB programming interfaces

There are three programmatic approaches, as follows, for accessing TimesTen LOBs in a C or C++ program.

- Simple data interface (ODBC, OCI, Pro*C/C++, TTClasses): Use binds and defines, as with other scalar types, to transfer LOB data in a single chunk.

- Piecewise data interface (ODBC): Use advanced forms of binds and defines to transfer LOB data in multiple pieces. This is sometimes referred to as *streaming* or using *data-at-exec* (at program execution time). TimesTen supports the piecewise data interface through polling loops to go piece-by-piece through the LOB data. (Another piecewise approach, using callback functions, is supported by Oracle Database but not by TimesTen.)

- LOB locator interface (OCI, Pro*C/C++): Select LOB locators using SQL then access LOB data through APIs that are similar conceptually to those used in accessing a file system. Using the LOB locator interface, you can work with LOB data in pieces or in single chunks. (See "LOBs in TimesTen OCI" on page 3-19 and "LOBs in TimesTen Pro*C/C++" on page 4-10.)

The LOB locator interface offers the most utility if it is feasible for you to use it.

Using the LOB simple data interface in ODBC

The simple data interface enables applications to access LOB data by binding and defining, just as with other scalar types. For the simple data interface in ODBC, use `SQLBindParameter` to bind parameters and `SQLBindCol` to define result columns. The application can bind or define using a SQL type that is compatible with the corresponding variable type, as follows:

- For BLOB data, use SQL type `SQL_LONGVARBINARY` and C type `SQL_C_BINARY`.

- For CLOB data, use SQL type `SQL_LONGVARCHAR` and C type `SQL_C_CHAR`.

- For NCLOB data, use SQL type `SQL_WLONGVARCHAR` and C type `SQL_C_WCHAR`.

`SQLBindParameter` and `SQLBindCol` calls for LOB data would be very similar to such calls for other data types, discussed earlier in this chapter.

> **Note:** Binding a CLOB or NCLOB with a C type of `SQL_C_BINARY` is prohibited.

Using the LOB piecewise data interface in ODBC

The piecewise interface enables applications to access LOB data in portions, piece by piece. An application binds parameters or defines results similarly to how those actions are performed for the simple data interface, but indicates that the data is to be provided or retrieved at program execution time ("at exec"). In TimesTen, you can

implement the piecewise data interface through a polling loop that is repeated until all the LOB data has been read or written.

For the piecewise data interface in ODBC, use SQLParamData with SQLPutData in a polling loop to bind parameters, as shown in Example 2–9 below, and SQLGetData in a polling loop to retrieve results. See the preceding section, "Using the LOB simple data interface in ODBC", for information about supported SQL and C data types for BLOBs, CLOBs, and NCLOBs.

> **Note:** Similar piecewise data access has already been supported for the various APIs in previous releases of TimesTen, for var data types.

Example 2–9   Using SQLPutData, ODBC piecewise data interface

This program excerpt uses SQLPutData with SQLParamData in a polling loop to insert LOB data piece-by-piece into the database. The CLOB column will contain the value "123ABC" when the code is executed.

```
...
/* create a table */
  create_stmt = "create table clobtable ( c clob )";
  rc = SQLExecDirect(hstmt, (SQLCHAR *)create_stmt, SQL_NTS);
  if(rc != SQL_SUCCESS){/* ...error handling... */}

  /* initialize an insert statement */
  insert_stmt = "insert into clobtable values(?)";
  rc = SQLPrepare(hstmt, (SQLCHAR *)insert_stmt, SQL_NTS);
  if(rc != SQL_SUCCESS){/* ...error handling... */}

  /* bind the parameter and specify that we will be using
   * SQLParamData/SQLPutData */
  rc = SQLBindParameter
    hstmt,             /* statement handle */
    1,                 /* colnum number */
    SQL_PARAM_INPUT,   /* param type */
    SQL_C_CHAR,        /* C type */
    SQL_LONGVARCHAR,   /* SQL type (ignored) */
    2,                 /* precision (ignored) */
    0,                 /* scale (ignored) */
    0,                 /* putdata token */
    0,                 /* ignored */
    &pcbvalue);        /* indicates use of SQLPutData */
  if(rc != SQL_SUCCESS){/* ...error handling... */}

  pcbvalue = SQL_DATA_AT_EXEC;

  /* execute the statement -- this should return SQL_NEED_DATA */
  rc = SQLExecute(hstmt);
  if(rc != SQL_NEED_DATA){/* ...error handling... */}

  /* while we still have parameters that need data... */
  while((rc = SQLParamData(hstmt, &unused)) == SQL_NEED_DATA){

    memcpy(char_buf, "123", 3);
    rc = SQLPutData(hstmt, char_buf, 3);
    if(rc !=  SQL_SUCCESS){/* ...error handling... */}

    memcpy(char_buf, "ABC", 3);
    rc = SQLPutData(hstmt, char_buf, 3);
```

```
            if(rc !=  SQL_SUCCESS){/* ...error handling... */}

    }
...
```

Passthrough LOBs in ODBC

Passthrough LOBs, which are LOBs in Oracle Database accessed through TimesTen, are exposed as TimesTen LOBs and are supported by TimesTen in much the same way that any TimesTen LOB is supported, but note the following:

- TimesTen LOB size limitations do not apply to storage of passthrough LOBs, but do apply to binding.

- As with TimesTen local LOBs, a passthrough LOB used in an application does not remain valid past the end of the transaction.

Making and committing changes to the database

Autocommit is enabled by default (according to the ODBC specification), so that any DML change you make, such as an update, insert, or delete, is committed automatically. It is recommended, however, that you disable this feature and commit (or roll back) your changes explicitly. Use the SQL_AUTOCOMMIT option in a SQLSetConnectOption call to accomplish this:

```
rc = SQLSetConnectOption(hdbc, SQL_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF);
```

With autocommit disabled, you can commit or roll back a transaction using the SQLTransact ODBC function, such as in the following example to commit:

```
rc = SQLTransact(henv, hdbc, SQL_COMMIT);
```

Refer to ODBC API reference documentation for details about these functions.

> **Notes:**
>
> - Autocommit mode applies only to the top-level statement executed by SQLExecute or SQLExecDirect. There is no awareness of what occurs inside the statement, and therefore no capability for intermediate autocommits of nested operations.
>
> - All open cursors on the connection are closed upon transaction commit or rollback in TimesTen.
>
> - The SQLRowCount function can be used to return information about SQL operations. For UPDATE, INSERT, and DELETE statements, the output argument returns the number of rows affected. See "Managing cache groups" on page 2-31 regarding special TimesTen functionality. Refer to ODBC API reference documentation for general information about SQLRowCount and its arguments.

You can refer to "Transaction overview" in *Oracle TimesTen In-Memory Database Operations Guide* for additional information about transactions.

Example 2–10   Updating the database and committing the change

This example prepares and executes a statement to give raises to selected employees, then manually commits the changes. Assume autocommit has been previously disabled.

```
update_example(SQLHDBC hdbc)
{
  SQLCHAR*      stmt_text;
  SQLHSTMT      hstmt;
  SQLINTEGER    raise_pct;
  char          hiredate_str[30];
  SQLLEN        hiredate_len;
  SQLLEN        numrows;

  /* allocate a statement handle */
  SQLAllocStmt(hdbc, &hstmt);

  /* prepare an update statement to give raises to employees hired before a
   * given date */
  stmt_text = (SQLCHAR*)
    "update employees "
    "set salary = salary * ((100 + :raise_pct) / 100.0) "
    "where hire_date < :hiredate";
  SQLPrepare(hstmt, stmt_text, SQL_NTS);

  /* bind parameter 1 (:raise_pct) to variable raise_pct */
  SQLBindParameter(hstmt, 1, SQL_PARAM_INPUT, SQL_C_SLONG,
                   SQL_DECIMAL, 0, 0, (SQLPOINTER)&raise_pct, 0, 0);

  /* bind parameter 2 (:hiredate) to variable hiredate_str */
  SQLBindParameter(hstmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR,
                   SQL_TIMESTAMP, 0, 0, (SQLPOINTER)hiredate_str,
                   sizeof(hiredate_str), &hiredate_len);

  /* set parameter values to give a 10% raise to employees hired before
   * January 1, 1996. */
  raise_pct = 10;
  strcpy(hiredate_str, "1996-01-01");
  hiredate_len = SQL_NTS;

  /* execute the update statement */
  SQLExecute(hstmt);

  /* print the number of employees who got raises  */
  SQLRowCount(hstmt, &numrows);
  printf("Gave raises to %d employees.\n", numrows);

  /* drop the statement handle */
  SQLFreeStmt(hstmt, SQL_DROP);

  /* commit the changes */
  SQLTransact(henv, hdbc, SQL_COMMIT);

}
```

Using additional TimesTen data management features

Preceding sections discussed key features for managing TimesTen data. This section covers the additional features listed here.

- [Using CALL to execute procedures and functions](#)
- [Setting a timeout or threshold for executing SQL statements](#)
- [Features for use with IMDB cache](#)
- [Setting globalization options](#)
- [Features for use with replication](#)
- [ODBC 3.0 data types](#)

Using CALL to execute procedures and functions

TimesTen supports each of the following syntax formats from any of its programming interfaces to call PL/SQL procedures (*procname*) or PL/SQL functions (*funcname*) that are standalone or part of a package, or to call TimesTen built-in procedures (*procname*).

```
CALL procname[(argumentlist)]

CALL funcname[(argumentlist)] INTO :returnparam

CALL funcname[(argumentlist)] INTO ?
```

TimesTen ODBC also supports each of the following syntax formats:

```
{ CALL procname[(argumentlist)] }

{ ? = [CALL] funcname[(argumentlist)] }

{ :returnparam = [CALL] funcname[(argumentlist)] }
```

The following ODBC example calls the TimesTen `ttCkpt` built-in procedure.

```
rc = SQLExecDirect (hstmt, (SQLCHAR*) "call ttCkpt",SQL_NTS);
```

These examples call a PL/SQL procedure `myproc` with two parameters:

```
rc = SQLExecDirect(hstmt, (SQLCHAR*) "{ call myproc(:param1, :param2) }",SQL_NTS);

rc = SQLExecDirect(hstmt, (SQLCHAR*) "{ call myproc(?, ?) }",SQL_NTS);
```

The following shows several ways to call a PL/SQL function `myfunc`:

```
rc = SQLExecDirect (hstmt, (SQLCHAR*) "CALL myfunc() INTO :retparam",SQL_NTS);

rc = SQLExecDirect (hstmt, (SQLCHAR*) "CALL myfunc() INTO ?",SQL_NTS);

rc = SQLExecDirect (hstmt, (SQLCHAR*) "{ :retparam = myfunc() }",SQL_NTS);

rc = SQLExecDirect (hstmt, (SQLCHAR*) "{ ? = myfunc() }",SQL_NTS);
```

See "CALL" in *Oracle TimesTen In-Memory Database SQL Reference* for details about `CALL` syntax.

Note:

- A user's own procedure takes precedence over a TimesTen built-in procedure with the same name, but it is best to avoid such naming conflicts.

- TimesTen does not support using `SQL_DEFAULT_PARAM` with `SQLBindParameter` for a `CALL` statement.

Setting a timeout or threshold for executing SQL statements

TimesTen offers two ways to limit the time for SQL statements or procedure calls to execute, applying to any `SQLExecute`, `SQLExecDirect`, or `SQLFetch` call.

- Setting a timeout duration for SQL statements
- Setting a threshold duration for SQL statements

For the former, if the timeout duration is reached, the statement stops executing and an error is thrown. For the latter, if the threshold is reached, an SNMP trap is thrown but execution continues.

Setting a timeout duration for SQL statements

To control how long SQL statements should execute before timing out, you can set the `SQL_QUERY_TIMEOUT` option using a `SQLSetStmtOption` or `SQLSetConnectOption` call to specify a timeout value, in seconds. A value of 0 indicates no timeout. Despite the name, this timeout value applies to any executable SQL statement, not just queries.

In TimesTen, you can specify this timeout value for a connection, and therefore any statement on the connection, by using the `SqlQueryTimeout` general connection attribute. (Also see "SqlQueryTimeout" in *Oracle TimesTen In-Memory Database Reference*.) A call to `SQLSetConnectOption` with the `SQL_QUERY_TIMEOUT` option overrides any previous query timeout setting. A call to `SQLSetStmtOption` with the `SQL_QUERY_TIMEOUT` option overrides the connection setting for the particular statement.

The query timeout limit has effect only when a SQL statement is actively executing. A timeout does not occur during commit or rollback. For transactions that update, insert, or delete a large number of rows, the commit or rollback phases may take a long time to complete. During that time the timeout value is ignored.

Notes:

- If you are using TimesTen Client/Server, the SQL query timeout should be significantly less than `TTC_Timeout`, and cannot be 0 (for no timeout) if `TTC_Timeout` is greater than 0. For details, see "TTC_Timeout" in *Oracle TimesTen In-Memory Database Reference*.

- If both a lock timeout value and a SQL query timeout value are specified, the lesser of the two values causes a timeout first. Regarding lock timeouts, you can refer to "ttLockWait" (built-in procedure) or "LockWait" (general connection attribute) in *Oracle TimesTen In-Memory Database Reference*, or to "Check for deadlocks and timeouts" in *Oracle TimesTen In-Memory Database Troubleshooting Guide*.

Setting a threshold duration for SQL statements

You can configure TimesTen to write a warning to the support log and throw an SNMP trap when the execution of a SQL statement exceeds a specified time duration, in seconds. Execution continues and is not affected by the threshold.

The name of the SNMP trap is `ttQueryThresholdWarnTrap`. See *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps* for information about configuring SNMP traps. Despite the name, this threshold applies to any executable SQL statement.

By default, the application obtains the threshold from the `QueryThreshold` general connection attribute setting (refer to "QueryThreshold" in *Oracle TimesTen In-Memory Database Reference*). Setting the `TT_QUERY_THRESHOLD` option in a `SQLSetConnectOption` call overrides the connection attribute setting for the current connection.

To set the threshold with `SQLSetConnectOption`:

```
RETCODE SQLSetConnectOption(hdbc, TT_QUERY_THRESHOLD, seconds);
```

Setting the `TT_QUERY_THRESHOLD` option in a `SQLSetStmtOption` call overrides the connection attribute setting, and any setting through `SQLSetConnectOption`, for the statement. It applies to SQL statements executed using the ODBC statement handle.

To set the threshold with `SQLSetStmtOption`:

```
RETCODE SQLSetStmtOption(hstmt, TT_QUERY_THRESHOLD, seconds);
```

You can retrieve the current value of `TT_QUERY_THRESHOLD` by using the `SQLGetConnectOption` or `SQLGetStmtOption` ODBC function:

```
RETCODE SQLGetConnectOption(hdbc, TT_QUERY_THRESHOLD, paramvalue);
```

```
RETCODE SQLGetStmtOption(hstmt, TT_QUERY_THRESHOLD, paramvalue);
```

Features for use with IMDB cache

This section discusses features related to the use of IMDB Cache:

- Setting temporary passthrough level with the ttOptSetFlag built-in procedure
- Determining passthrough status
- Managing cache groups

See *Oracle In-Memory Database Cache User's Guide* for information about IMDB Cache.

See "PassThrough" in *Oracle TimesTen In-Memory Database Reference* for information about that general connection attribute. See "Setting a passthrough level" in *Oracle In-Memory Database Cache User's Guide* for information about passthrough settings.

Setting temporary passthrough level with the ttOptSetFlag built-in procedure

TimesTen provides the `ttOptSetFlag` built-in procedure for setting various flags, including the `PassThrough` flag to temporarily set the passthrough level. You can use `ttOptSetFlag` to set `PassThrough` in a C application as in the following example, which sets the passthrough level to 1. The setting affects all statements that are prepared until the end of the transaction.

```
rc = SQLExecDirect (hstmt, "ttOptSetFlag ('PassThrough', 1)",SQL_NTS);
```

See "ttOptSetFlag" in *Oracle TimesTen In-Memory Database Reference* for more information about that built-in procedure.

Determining passthrough status

You can call the `SQLGetStmtOption` ODBC function with the `TT_STMT_PASSTHROUGH_TYPE` statement option to determine whether a SQL statement is to be executed in the TimesTen database or passed through to the Oracle database for execution. For example:

```
rc = SQLGetStmtOption(hStmt, TT_STMT_PASSTHROUGH_TYPE, &passThroughType);
```

You can make this call after preparing the SQL statement. It is useful with `PassThrough` settings of 1, 2, 4, or 5, where the determination of whether a statement will actually be passed through is not made until compilation time. If `TT_STMT_PASSTHROUGH_NONE` is returned, the statement is to be executed in TimesTen. If `TT_STMT_PASSTHROUGH_ORACLE` is returned, the statement is to be passed through to Oracle for execution.

> **Note:** `TT_STMT_PASSTHROUGH_TYPE` is supported with `SQLGetStmtOption` only, not with `SQLSetStmtOption`.

Managing cache groups

In IMDB Cache, following the execution of a `FLUSH CACHE GROUP`, `LOAD CACHE GROUP`, `REFRESH CACHE GROUP`, or `UNLOAD CACHE GROUP` statement, the ODBC function `SQLRowCount` returns the number of cache instances that were flushed, loaded, refreshed, or unloaded.

For related information, see "Determining the number of cache instances affected by an operation" in *Oracle In-Memory Database Cache User's Guide*.

Refer to ODBC API reference documentation for general information about `SQLRowCount`.

Setting globalization options

TimesTen extensions to ODBC enable an application to set options for linguistic sorts, length semantics for character columns, and error reporting during character set conversion. These options can be used in a call to `SQLSetConnectOption`. The options are defined in the `timesten.h` file (noted in "TimesTen include files" on page 2-7).

For more information about linguistic sorts, length semantics, and character sets, see "Globalization Support" in *Oracle TimesTen In-Memory Database Operations Guide*.

This section includes the following TimesTen ODBC globalization options.

- TT_NLS_SORT
- TT_NLS_LENGTH_SEMANTICS
- TT_NLS_NCHAR_CONV_EXCP

TT_NLS_SORT

This option specifies the collating sequence used for linguistic comparisons. See "Monolingual linguistic sorts" and "Multilingual linguistic sorts" in *Oracle TimesTen In-Memory Database Operations Guide* for supported linguistic sorts.

It takes a string value. The default is "BINARY".

Also see the description of the `NLS_SORT` general connection attribute, which has the same functionality, in "NLS_SORT" in *Oracle TimesTen In-Memory Database Reference*.

Note that `TT_NLS_SORT`, being a runtime option, takes precedence over the `NLS_SORT` connection attribute.

TT_NLS_LENGTH_SEMANTICS

This option specifies whether byte or character semantics is used. The possible values are:

- `TT_NLS_LENGTH_SEMANTICS_BYTE` (default)

- `TT_NLS_LENGTH_SEMANTICS_CHAR`

Also see the description of the `NLS_LENGTH_SEMANTICS` general connection attribute, which has the same functionality, in "NLS_LENGTH_SEMANTICS" in *Oracle TimesTen In-Memory Database Reference*. Note that `TT_NLS_LENGTH_SEMANTICS`, being a runtime option, takes precedence over the `NLS_LENGTH_SEMANTICS` connection attribute.

TT_NLS_NCHAR_CONV_EXCP

This option specifies whether an error is reported when there is data loss during an implicit or explicit character type conversion between `NCHAR` or `NVARCHAR2` data and `CHAR` or `VARCHAR2` data during SQL operations. The option does not apply to conversions done by ODBC as a result of binding.

The possible values are:

- `TRUE`: Errors during conversion are reported.

- `FALSE`: Errors during conversion are not reported (default).

Also see the description of the `NLS_NCHAR_CONV_EXCP` general connection attribute, which has the same functionality, in "NLS_NCHAR_CONV_EXCP" in *Oracle TimesTen In-Memory Database Reference*. Note that `TT_NLS_NCHAR_CONV_EXCP`, being a runtime option, takes precedence over the `NLS_NCHAR_CONV_EXCP` connection attribute.

Features for use with replication

For applications that employ replication, you can improve performance by using *parallel replication*, which uses multiple threads acting in parallel to replicate and apply transactional changes to nodes in a replication scheme. TimesTen supports two types of parallel replication: automatic and user-defined.

Automatic parallel replication enforces transactional dependencies and applies changes in commit order.

In user-defined parallel replication, there are user-defined *tracks* of transactions that operate in parallel. The application assigns transactions to tracks and specifies which track a transaction belongs to when the transaction starts on the source database. The transactions in each track are applied in the order in which they are received on the target database, but commit order is not maintained for transactions across the different tracks. You can use user-defined parallel replication if your application has predictable transactional dependencies and does not require the commit order on the target database to be the same as the order on the source database.

See "Configuring parallel replication" in *Oracle TimesTen In-Memory Database Replication Guide* for additional information and usage scenarios.

> **Note:** Automatic parallel replication is generally advisable over user-defined parallel replication. With user-defined parallel replication, care must be taken to avoid data divergence between replication nodes.

In an ODBC application with user-defined parallel replication, specify the track number for transactions on a connection through the `TT_REPLICATION_TRACK` connection option, as noted in "Option support for SQLSetConnectOption and SQLGetConnectOption" on page 10-3. (Alternatively, use the general connection attribute `ReplicationTrack` or the `ALTER SESSION` parameter `REPLICATION_TRACK`.)

ODBC 3.0 data types

The data types used in ODBC 2.0 and prior have been renamed in ODBC 3.0 for ISO 92 standards compliance. The sample programs shipped with TimesTen have been written using SQL 3.0 data types. The following table maps 2.0 types to their 3.0 equivalents.

Note that TimesTen supports ODBC 2.5, Extension Level 1, with additional features for Extension Level 2 where those features are included in Chapter 10, "TimesTen ODBC Functions and Options".

ODBC 2.0 data type	ODBC 3.0 data type
HDBC	SQLHDBC
HENV	SQLHENV
HSTMT	SQLHSTMT
HWND	SQLHWND
LDOUBLE	SQLDOUBLE
RETCODE	SQLRETURN
SCHAR	SQLSCHAR
SDOUBLE	SQLFLOATS
SDWORD	SQLINTEGER
SFLOAT	SQLREAL
SWORD	SQLSMALLINT
UCHAR	SQLCHAR
UDWORD	SQLUINTEGER
UWORD	SQLUSMALLINT

Either version of data types may be used with TimesTen without restriction.

Note also that the `FAR` modifier that is mentioned in ODBC 2.0 documentation is not required.

Considering TimesTen features for access control

TimesTen has features to control database access with object-level resolution for database objects such as tables, views, materialized views, sequences, and synonyms.

You can refer to "Managing Access Control" in *Oracle TimesTen In-Memory Database Operations Guide* for introductory information about these features.

This section introduces access control as it relates to SQL operations, database connections, XLA, and C utility functions.

For any query or SQL DML or DDL statement discussed in this document or used in an example, it is assumed that the user has appropriate privileges to execute the statement. For example, a SELECT statement on a table requires ownership of the table, SELECT privilege granted for the table, or the SELECT ANY TABLE system privilege. Similarly, any DML statement requires table ownership, the applicable DML privilege (such as UPDATE) granted for the table, or the applicable ANY TABLE privilege (such as UPDATE ANY TABLE).

For DDL statements, CREATE TABLE requires the CREATE TABLE privilege in the user's schema, or CREATE ANY TABLE in any other schema. ALTER TABLE requires ownership or the ALTER ANY TABLE system privilege. DROP TABLE requires ownership or the DROP ANY TABLE system privilege. There are no object-level ALTER or DROP privileges.

Refer to "SQL Statements" in *Oracle TimesTen In-Memory Database SQL Reference* for the privilege required for any given SQL statement.

Privileges are granted through the SQL statement GRANT and revoked through the statement REVOKE. Some privileges are granted to all users through the PUBLIC role, of which each user is a member. See "The PUBLIC role" in *Oracle TimesTen In-Memory Database SQL Reference* for information about that role.

In addition, access control affects the following topics covered in this document:

- Connecting to a database: Refer to "Access control for connections" on page 2-6.

- Setting connection attributes: Refer to "Setting connection attributes programmatically" on page 2-6.

- Configuring and managing XLA and using XLA functions: Refer to "Access control impact on XLA" on page 5-8. Also refer to Chapter 9, "XLA Reference." The documentation for each XLA function notes the required privilege.

- Executing C utility functions: Refer to Chapter 8, "TimesTen Utility API." The documentation for each utility mentions whether any privilege is required.

Notes:

- Access control cannot be disabled.

- Access control privileges are checked both when SQL is prepared and when it is executed in the database, with most of the performance cost coming at prepare time.

Handling Errors

This section includes the following topics:

- Checking for errors

- Error and warning levels

- Recovering after fatal errors

Checking for errors

An application should check for errors and warnings on every call. This saves considerable time and effort during development and debugging. The demo programs provided with TimesTen show examples of error checking.

Errors can be checked using either the TimesTen error code (error number) or error string, as defined in the *install_dir*/include/tt_errCode.h file. Entries are in the following format:

```
#define tt_ErrMemoryLock        712
```

For a description of each message, see "List of errors and warnings" in *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps*.

After calling an ODBC function, check the return code. If the return code is not SQL_SUCCESS, use an error-handling routine that calls the ODBC function SQLError to retrieve the errors on the relevant ODBC handle. A single ODBC call may return multiple errors. The application should be written to return all errors by repeatedly calling the SQLError function until all errors are read from the error stack. Continue calling SQLError until the return code is SQL_NO_DATA_FOUND.

Refer to ODBC API reference documentation for details about the SQLError function and its arguments.

For more information about writing a function to handle standard ODBC errors, see "Retrieving errors and warnings" in *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps*.

Example 2–11   Checking an ODBC function call for errors

This example shows that after a call to SQLAllocConnect, you can check for an error condition. If one is found, an error message is displayed and program execution is terminated.

```
rc = SQLAllocConnect(henv, &hdbc);

if (rc != SQL_SUCCESS) {
  handleError(rc, henv, hdbc, hstmt, err_buf, &native_error);
  fprintf(stderr,
          "Unable to allocate a connection handle:\n%s\n",
          err_buf);
  exit(-1);
}
```

Error and warning levels

When operations are not completely successful, TimesTen can return fatal errors, non-fatal errors, or warnings.

Fatal errors

Fatal errors are those that make the database inaccessible until after error recovery. When a fatal error occurs, all database connections are required to disconnect. No further operations may complete. Fatal errors are indicated by TimesTen error codes 846 and 994. Error handling for these errors should be different from standard error handling. In particular, the application error-handling code should roll back the current transaction and disconnect from the database.

Also see "Recovering after fatal errors" on page 2-36.

Non-fatal errors

Non-fatal errors include simple errors such as an `INSERT` statement that violates unique constraints. This category also includes some classes of application and process failures.

TimesTen returns non-fatal errors through the normal error-handling process. Application should check for errors and appropriately handle them.

When a database is affected by a non-fatal error, an error may be returned and the application should take appropriate action.

An application can handle non-fatal errors by modifying its actions or, in some cases, rolling back one or more offending transactions.

Warnings

TimesTen returns warnings when something unexpected occurs that you may want to know about. Here are some events that cause TimesTen to issue a warning:

- Checkpoint failure

- Use of a deprecated TimesTen feature

- Truncation of some data

- Execution of a recovery process upon connect

- Replication return receipt timeout

Application developers should have code that checks for warnings, as they can indicate application problems.

Abnormal termination

In some cases, such as process failure, no error is returned, but TimesTen automatically rolls back the transactions of the failed process.

Recovering after fatal errors

When fatal errors occur, TimesTen performs a full cleanup and recovery procedure:

- Every connection to the database is invalidated. To avoid out-of-memory conditions in the server, applications are required to disconnect from the invalidated database. Shared memory from the old TimesTen instance will not be freed until all active connections at the time of the error have disconnected. Inactive applications still connected to the old TimesTen instance may have to be manually terminated.

- The database is recovered from the checkpoint and transaction log files upon the first subsequent initial connection.

- The recovered database reflects the state of all durably committed transactions and possibly some transactions that were committed non-durably.

- No uncommitted or rolled back transactions are reflected.

Using automatic client failover in your application

Automatic client failover is for use in High Availability scenarios with a TimesTen active standby pair replication configuration. If there is a failure of the active node, failover (transfer) to the new active (original standby) node occurs, and applications are automatically reconnected to the new active node. TimesTen provides features that

enable applications to be alerted when this happens, so they can take any appropriate action.

This section discusses the TimesTen implementation of automatic client failover as it applies to application developers, covering the following topics.

- Functionality of automatic client failover
- Configuration of automatic client failover
- Failover callback functions

See "Using automatic client failover" in *Oracle TimesTen In-Memory Database Operations Guide* for additional information about this feature.

Functionality of automatic client failover

When an application first connects to the active node, the connection is registered and this registration is replicated to the standby node. If the active node fails, the standby node becomes the new active node and then notifies the client of the failover. At this point, be aware of the following:

- The client will have a new connection to the new active node, but using the same ODBC connection handle as before. No state from the original connection, other than the handle itself, is preserved. The application must open new ODBC statement handles.

- There is a failover listener thread at each client that invokes the failover event function associated with your application, if a function has been registered. (See "Failover callback functions" on page 2-38.)

All client statement handles from the original connection are marked as invalid. API calls on these statement handles will generally return `SQL_ERROR` with a distinctive failover error code, defined in `tt_errCode.h`, such as:

```
SQLSTATE = S1000 "General Error", native error = tt_ErrFailoverInvalidation
```

The exception to this is for `SQLError` and `SQLFreeStmt` calls, which behave normally.

In addition, note the following:

- The socket to the original active node is closed. There is no attempt to call `SQLDisconnect`.

- In connecting to the new active (original standby) TimesTen node, the same connection string that was returned from the original connection request is used, except the new server DSN is specified.

- It is up to the application to open new statement handles and reexecute necessary `SQLPrepare` calls.

- If a failover has already occurred and the client is already connected to the new active node, the next failover request results in an attempt to reconnect to the original active node. If that fails, alternating attempts are made to connect to the two servers until there is a timeout, and the connection is blocked during this period. The timeout value is according to the TimesTen client connection attribute `TTC_Timeout` (default 60 seconds), but with a minimum value of 60 seconds regardless of the `TTC_Timeout` setting. (Refer to "TTC_Timeout" in *Oracle TimesTen In-Memory Database Reference* for information about that attribute.)

- Failover connections are created only as needed, not in advance.

When failover has completed, TimesTen makes a callback to a user-defined function that you register. This function takes care of any custom actions you want to occur in a failover situation.

The following public connection options will be propagated to the new connection. The corresponding general connection attribute is shown in parentheses where applicable. The `TT_REGISTER_FAILOVER_CALLBACK` option is used to register your callback function.

```
SQL_ACCESS_MODE
SQL_AUTOCOMMIT
SQL_TXN_ISOLATION (Isolation)
SQL_OPT_TRACE
SQL_QUIET_MODE
TT_PREFETCH_CLOSE
TT_CLIENT_TIMEOUT (TTC_TIMEOUT)
TT_REGISTER_FAILOVER_CALLBACK
```

The following options will be propagated to the new connection if they were set through connection attributes or `SQLSetConnectOption` calls, but not if set through TimesTen built-in procedures or `ALTER SESSION`.

```
TT_NLS_SORT (NLS_SORT)
TT_NLS_LENGTH_SEMANTICS (NLS_LENGTH_SEMANTICS)
TT_NLS_NCHAR_CONV_EXCP (NLS_NCHAR_CONV_EXCP)
TT_DYNAMIC_LOAD_ENABLE (DynamicLoadEnable)
TT_DYNAMIC_LOAD_ERROR_MODE (DynamicLoadErrorMode)
```

The following options will be propagated to the new connection if they were set on the connection handle.

```
SQL_QUERY_TIMEOUT
TT_PREFETCH_COUNT
```

Configuration of automatic client failover

Refer to "Configuring automatic client failover" in *Oracle TimesTen In-Memory Database Operations Guide* for information.

> **Note:** Setting any of `TTC_Server2`, `TTC_Server_DSN2`, or `TCP_Port2` implies the following:
>
> ■ You intend to use automatic client failover.
>
> ■ You understand that a new thread will be created for your application to support the failover mechanism.
>
> ■ You have linked your application with a thread library (pthreads on UNIX systems).

Failover callback functions

When failover occurs, TimesTen makes a callback to your user-defined function for any desired action. This function is called when the attempt to connect to the new active (original standby) node begins, and again after the attempt to connect is complete. This function could be used, for example, to cleanly restore statement handles.

The function API is defined as follows.

```
typedef SQLRETURN (*ttFailoverCallbackFcn_t)
  (SQLHDBC,      /* hdbc    */
   SQLPOINTER,   /* foCtx   */
   SQLUINTEGER,  /* foType  */
   SQLUINTEGER); /* foEvent */
```

Where:

- *hdbc* is the ODBC connection handle for the connection that failed.

- *foCtx* is a pointer to an application-defined data structure, for use as needed.

- *foType* is the type of failover. In TimesTen, the only supported value for this is
  TT_FO_SESSION, which results in the session being reestablished. This does not
  result in statements being re-prepared.

- *foEvent* indicates the event that has occurred, with the following supported
  values:

  - TT_FO_BEGIN: Beginning failover.

  - TT_FO_ABORT: Failover failed. Retries were attempted for the interval specified
    by TTC_Timeout (minimum value 60 seconds for active standby failover)
    without success.

  - TT_FO_END: Successful end of failover.

  - TT_FO_ERROR: A failover connection failed but will be retried.

  Note that TT_FO_REAUTH is *not* supported by TimesTen client failover.

Use a SQLSetConnectOption call to set the TimesTen TT_REGISTER_FAILOVER_CALLBACK
option to register the callback function, specifying an option value that is a pointer to a
structure of C type ttFailoverCallback_t, which is defined as follows in the
timesten.h file and refers to the callback function:

```
typedef struct{
  SQLHDBC                 appHdbc;
  ttFailoverCallbackFcn_t callbackFcn;
  SQLPOINTER              foCtx;
} ttFailoverCallback_t;
```

Where:

- *appHdbc* is the ODBC connection handle, and should have the same value as *hdbc*
  in the SQLSetConnectOption calling sequence. (It is required in the data structure
  due to driver manager implementation details, in case you are using a driver
  manager.)

- *callbackFcn* specifies the callback function. (You can set this to NULL to cancel
  callbacks for the given connection. The failover will still happen, but the
  application will not be notified.)

- *foCtx* is a pointer to an application-defined data structure, as in the function
  description earlier.

Set TT_REGISTER_FAILOVER_CALLBACK for each connection for which a callback is
desired. The values in the ttFailoverCallback_t structure will be copied when the
SQLSetConnectOption call is made. The structure need not be kept by the application.
If TT_REGISTER_FAILOVER_CALLBACK is set multiple times for a connection, the last
setting takes precedence.

> **Notes:**
>
> - Because the callback function executes asynchronously to the main thread of your application, it should generally perform only simple tasks, such as setting flags that are polled by the application. However, there is no such restriction if the application is designed for multithreading. In that case, the function could even make ODBC calls, for example, but it is only safe to do so if the *foEvent* value TT_FO_END has been received.
>
> - It is up to the application to manage the data pointed to by the *foCtx* setting.

Example 2–12 Failover callback function and registration

This example shows the following:

- A globally defined user structure type, FOINFO, and the structure variable foStatus of type FOINFO

- A callback function, FailoverCallback(), that updates the foStatus structure whenever there is a failover

- A registration function, RegisterCallback(), that does the following:

  – Declares a structure, failoverCallback, of type ttFailoverCallback_t.

  – Initializes foStatus values.

  – Sets the failoverCallback data values, consisting of the connection handle, a pointer to foStatus, and the callback function (FailoverCallback).

  – Registers the callback function with a SQLSetConnectOption call that sets TT_REGISTER_FAILOVER_CALLBACK as a pointer to failoverCallback.

```
/* user defined structure */
struct FOINFO
{
 int callCount;
 SQLUINTEGER lastFoEvent;
};
/* global variable passed into the callback function */
struct FOINFO foStatus;

/* the callback function */
SQLRETURN FailoverCallback (SQLHDBC hdbc,
                            SQLPOINTER pCtx,
                            SQLUINTEGER FOType,
                            SQLUINTEGER FOEvent)
{
 struct FOINFO* pFoInfo = (struct FOINFO*) pCtx;

 /* update the user defined data */
 if (pFoInfo != NULL)
 {
   pFoInfo->callCount ++;
   pFoInfo->lastFoEvent = FOEvent;

   printf ("Failover Call #%d\n", pFoInfo->callCount);
 }

 /* the ODBC connection handle */
```

```
      printf ("Failover HDBC : %p\n", hdbc);

      /* pointer to user data */
      printf ("Failover Data : %p\n", pCtx);

      /* the type */
      switch (FOType)
      {
        case TT_FO_SESSION:
          printf ("Failover Type : TT_FO_SESSION\n");
          break;

        default:
          printf ("Failover Type : (unknown)\n");
      }

      /* the event */
      switch (FOEvent)
      {
        case TT_FO_BEGIN:
          printf ("Failover Event: TT_FO_BEGIN\n");
          break;

        case TT_FO_END:
          printf ("Failover Event: TT_FO_END\n");
          break;

        case TT_FO_ABORT:
          printf ("Failover Event: TT_FO_ABORT\n");
          break;

        case TT_FO_REAUTH:
          printf ("Failover Event: TT_FO_REAUTH\n");
          break;

        case TT_FO_ERROR:
          printf ("Failover Event: TT_FO_ERROR\n");
          break;

        default:
          printf ("Failover Event: (unknown)\n");
      }

      return SQL_SUCCESS;
    }

    /* function to register the callback with the failover connection */
    SQLRETURN RegisterCallback (SQLHDBC hdbc)
    {
      SQLRETURN rc;
      ttFailoverCallback_t failoverCallback;

      /* initialize the global user defined structure */
      foStatus.callCount = 0;
      foStatus.lastFoEvent = -1;

      /* register the connection handle, callback and the user defined structure */
      failoverCallback.appHdbc = hdbc;
      failoverCallback.foCtx = &foStatus;
      failoverCallback.callbackFcn = FailoverCallback;
```

```
 rc = SQLSetConnectOption (hdbc, TT_REGISTER_FAILOVER_CALLBACK,
    (SQLULEN)&failoverCallback);

 return rc;
}
```

When a failover occurs, the callback function would produce output such as the following:

```
Failover Call #1
Failover HDBC : 0x8198f50
Failover Data : 0x818f8ac
Failover Type : TT_FO_SESSION
Failover Event: TT_FO_BEGIN
```

3

TimesTen Support for OCI

TimesTen and Oracle IMDB Cache support the Oracle Call Interface (OCI) for C or C++ programs.

This chapter provides an overview and TimesTen-specific information regarding OCI, especially emphasizing differences between using OCI with TimesTen versus with Oracle Database. For complete information about OCI, you can refer to *Oracle Call Interface Programmer's Guide* in the Oracle Database library.

Also note that Chapter 2, "Working with TimesTen Databases in ODBC", contains information that may be of general interest regarding TimesTen features.

The following topics are covered:

- Overview of OCI
- Overview of TimesTen OCI support
- Getting started with TimesTen OCI
- Additional features of TimesTen OCI
- TimesTen OCI support reference

Overview of OCI

OCI is an API that provides functions you can use to access the database server and control SQL execution. OCI supports the data types, calling conventions, syntax, and semantics of the C and C++ programming languages. You compile and link an OCI program much as you would any C or C++ program. There is no preprocessing or precompilation step.

The OCI library of database access and retrieval functions is in the form of a dynamic runtime library that can be linked into an application at runtime. The OCI library includes the following functional areas:

- SQL access functions
- Data type mapping and manipulation functions

The following are among the many useful features that OCI provides or supports:

- Statement caching
- Dynamic SQL
- Facilities to treat transaction control, session control, and system control statements like DML statements
- Description functionality to expose layers of server metadata

- Ability to associate commit requests with statement executions to reduce round trips

- Optimization of queries using transparent prefetch buffers to reduce round trips

- Thread safety that eliminates the need for mutual exclusive locks on OCI handles

For general information about OCI, you can refer to *Oracle Call Interface Programmer's Guide*, included with the Oracle Database documentation set.

Overview of TimesTen OCI support

This chapter contains information specific to using OCI with TimesTen and IMDB Cache. For supported features, TimesTen OCI syntax and usage is the same as that in Oracle Database.

This section covers the following topics:

- OCI libraries and architecture

- Globalization support

- TimesTen restrictions and differences

- The ttSrcScan utility

OCI libraries and architecture

TimesTen OCI depends on the Oracle Database client library and the TimesTen ODBC libraries. TimesTen OCI support enables you to run many existing OCI applications with TimesTen direct connections or client/server connections. It also enables you to use other Oracle Database products, such as Pro*C/C++ and ODP.NET, that use OCI as a database interface. (You can also call PL/SQL from OCI, Pro*C/C++, and ODP.NET applications.) Figure 3–1 shows where OCI support is positioned in the TimesTen architecture.

TimesTen provides Oracle Instant Client as the OCI client library. This is configured through the appropriate `ttenv` script, as discussed in "Setting the environment for development" on page 1-1.

Figure 3–1   OCI in the TimesTen architecture
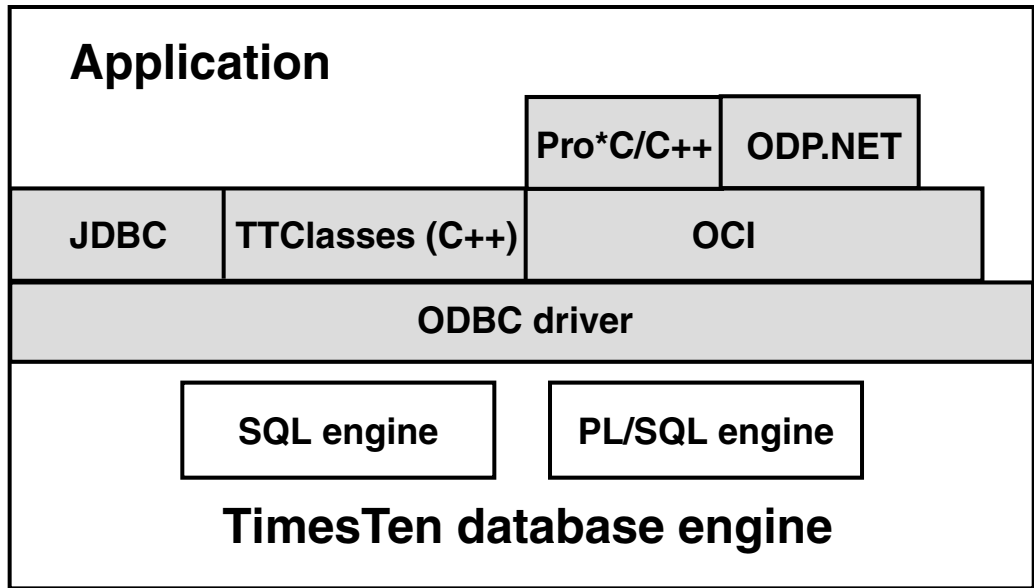

TimesTen 11*g* Release 2 (11.2.2) OCI is based on Oracle Database release 11.2.0.2 OCI and supports the contemporary OCI 8 style APIs. For example, the `OCIStmtExecute()` function is supported but not the older `oexec()` function. See "Obsolete OCI Routines" in *Oracle Call Interface Programmer's Guide* in the Oracle Database documentation.

Globalization support

This section discusses TimesTen OCI support for globalization.

Character sets

To specify a character set for the connection, OCI programs can set the `NLS_LANG` environment variable or call `OCIEnvNlsCreate()`. The setting in the `sys.odbc.ini` or user `odbc.ini` file is used by default if not overridden by `NLS_LANG` or `OCIEnvNlsCreate()`. Setting the character set explicitly is recommended. The default is typically `AMERICAN_AMERICA.US7ASCII`.

Note that because TimesTen OCI does not support language or locale (territory) settings, the language and territory components of `NLS_LANG`, such as `AMERICAN_AMERICA` above, are ignored. Even when not specifying the language and locale, however, you must still have the period in front of the character set when setting `NLS_LANG`. For example, either of the following would work, although `AMERICAN_AMERICA` is ignored:

```
NLS_LANG=AMERICAN_AMERICA.WE8ISO8859P1
```

Or:

```
NLS_LANG=.WE8ISO8859P1
```

> **Notes:**
>
> - An `NLS_LANG` environment setting overrides the TimesTen default character set.
>
> - The `TIMESTEN8` character set is not supported.
>
> - On Windows, the `NLS_LANG` setting is searched for in the registry if it is not in the environment. If your OCI or Pro*C/C++ program has trouble connecting to TimesTen, verify that the `NLS_LANG` setting under `HKEY_LOCAL_MACHINE\Software\ORACLE\`, if that key exists, is valid and indicates a character set supported by TimesTen. (The `NLS_LANG` registry setting may not exist or may be set to an invalid value, such as "`NA`". In these cases, the TimesTen installer will use `AMERICAN_AMERICA.US7ASCII`.) This is likely only an issue on systems that previously had Oracle9*i* or earlier Oracle Database versions installed.
>
> - Refer to "Choosing a Locale with the NLS_LANG Environment Variable" in *Oracle Database Globalization Support Guide* for information about `NLS_LANG`.
>
> - Refer to "OCIEnvNlsCreate()" in *Oracle Call Interface Programmer's Guide* for information about that OCI call.

Additional globalization features

TimesTen OCI also supports the following additional globalization features. These can be set as environment variables, TimesTen general connection attributes, or TimesTen ODBC connection options. For the connection options, the names here are prepended by "`TT_`". An environment variable setting takes precedence over a corresponding connection attribute or connection option setting. A connection option setting takes precedence over a corresponding connection attribute setting.

- `NLS_LENGTH_SEMANTICS`: By default, the lengths of character data types `CHAR` and `VARCHAR2` are specified in bytes, not characters. For single-byte character encoding this works well. For multibyte character encoding, you can use `NLS_LENGTH_SEMANTICS` to create `CHAR` and `VARCHAR2` columns using character-length semantics instead. Supported settings are `BYTE` (default) and `CHAR`. (`NCHAR` and `NVARCHAR2` columns are always character-based. Existing columns are not affected.)

- `NLS_SORT`: This specifies the type of sort for character data. It overrides the default value from `NLS_LANGUAGE`. Valid values are `BINARY` or any linguistic sort name supported by TimesTen. For example, to specify the German linguistic sort sequence, set `NLS_SORT=German`.

- `NLS_NCHAR_CONV_EXCP`: This determines whether an error is reported when there is data loss during an implicit or explicit character type conversion between `NCHAR` or `NVARCHAR` data and `CHAR` or `VARCHAR2` data. Valid settings are `TRUE` and `FALSE`. The default value is `FALSE`, resulting in no error being reported.

Refer to "Globalization Support" in *Oracle TimesTen In-Memory Database Operations Guide* and "Setting Up a Globalization Support Environment" in *Oracle Database Globalization Support Guide* for additional information on these environment variables and related features. See "Option support for SQLSetConnectOption and SQLGetConnectOption" on page 10-3 for information about TimesTen connection option support.

TimesTen restrictions and differences

This section discusses the following areas of restrictions and differences for OCI in TimesTen compared to in the Oracle Database:

- Oracle Database features not supported

- Additional TimesTen OCI restrictions

- Additional TimesTen OCI differences

Oracle Database features not supported

TimesTen does not support OCI calls that are related to functionality that does not exist in TimesTen or IMDB Cache. For example, TimesTen and IMDB Cache do not support these Oracle Database features:

- Advanced Queuing

- Any Data

- Object support

- Collections

- Cartridge Services

- Direct path loading

- Date/time intervals

- Iterators

- BFILEs

- Cryptographic Toolkit

- XML DB support

- Spatial Services

- Event handling

- Session switching

- Scrollable cursors

Additional TimesTen OCI restrictions

TimesTen OCI has the following restrictions:

- The `TypeMode` data store attribute must be set to 0, which corresponds to Oracle Database behavior.

- The `DuplicateBindMode` general connection attribute must be set to 0, which corresponds to Oracle Database behavior.

- The `DDLCommitBehavior` general connection attribute must be set to 0, which corresponds to Oracle Database behavior.

- Asynchronous calls are not supported.

- Connection pooling and session pooling are not supported.

- Describing objects with `OCIDescribeAny()` is supported only by name. Describing PL/SQL objects is not supported. (Also see the entry for this function under "Supported OCI calls" on page 3-30.)

- TimesTen Client/Server automatic client failover is not supported.

- The `TNSPING` utility does not recognize connections to TimesTen.

- Retrieving implicit `ROWID` values from `INSERT`, `UPDATE`, and `DELETE` statements is not supported. (This is supported for `SELECT FOR UPDATE` statements, however.)

- TimesTen built-in procedures that return result sets are not supported directly.

- Only a single REF CURSOR can be returned from a PL/SQL block, procedure call, or function call.

- Binding and defining of structures through `OCIBindArrayOfStruct()` and `OCIDefineArrayOfStruct()` is supported for SQL statements but not for PL/SQL. (Also see the entries for these functions under "Supported OCI calls" on page 3-30.)

- Oracle Database utilities such as SQL*Plus and SQL*Loader are not supported. (In TimesTen, you can use `ttIsql` instead of SQL*Plus and `ttBulkCp` instead of SQL*Loader. See "Utilities" in *Oracle TimesTen In-Memory Database Reference*.)

- Array binding, the ability to bind arrays into PL/SQL statements, is supported for associative arrays (index-by tables or PL/SQL tables) but is *not* supported for varrays (variable size arrays) or nested tables. (See "Associative array bindings in TimesTen OCI" on page 3-13.)

Additional TimesTen OCI differences

Be aware of the following:

- Both TimesTen and Oracle Database support XA, but TimesTen does not support XA through OCI.

- With OCI, TimesTen automatically disables autocommit for DML statements. Transactions should be explicitly committed or rolled back when finished.

- There are differences in the usage of hexadecimal literals in TimesTen. See the description of *HexadecimalLiteral* in "Constants" in *Oracle TimesTen In-Memory Database SQL Reference*.

The ttSrcScan utility

If you have an existing OCI program and want to see whether it uses OCI features that TimesTen does not support, you can use the `ttSrcScan` command line utility to scan your program for unsupported functions, types, type codes, attributes, modes, and constants. This is a standalone utility that can be run without TimesTen or Oracle Database being installed and runs on any platform supported by TimesTen. It reads source code files as input and creates HTML and text files as output. If the utility finds unsupported items, then they are logged and alternatives are suggested. You can find the `ttSrcScan` executable in the `quickstart/sample_util` directory in your TimesTen installation.

Specify an input file or directory for the program to be scanned and an output directory for the `ttSrcScan` reports. Other options are available as well. See the README file in the `sample_util` directory for information.

Getting started with TimesTen OCI

This section discusses the following topics for getting started with a TimesTen OCI application:

- Environment variables for TimesTen OCI

- Compiling and linking OCI applications
- Connecting to a TimesTen database from OCI
- Error reporting
- Signal handling and diagnostic framework considerations
- OCI demo programs

Environment variables for TimesTen OCI

Environment variables for executing a TimesTen OCI application are described in Table 3–1. Settings apply to both direct connections and client/server connections except as noted.

After installation, you can modify environment variables as appropriate through the TimesTen *install_dir*/bin/ttenv script or quickstart/ttquickstartenv script applicable to your operating system. Also see "Setting the environment for development" on page 1-1.

You can also use the TimesTen OCI and Pro*C/C++ Makefiles provided with the Quick Start demos to implement appropriate environment settings. These are in the following locations:

```
quickstart/sample_code/oci/
quickstart/sample_code/proc/
```

Refer to "Environment variables" in *Oracle TimesTen In-Memory Database Installation Guide* for additional information about environment variables and ttenv.

Note: To ensure proper generation of OCI programs to be run on TimesTen, do not set ORACLE_HOME (or unset it if it was set previously) for OCI compilations.

Table 3–1   Environment variables for TimesTen OCI

Variable	Required or optional	Settings
LD_LIBRARY_PATH (UNIX) PATH (Windows)	Required	Must be set so that the TimesTen Instant Client directory precedes the Oracle Database libraries in the path. The path will be set properly if you use either of the following scripts under *install_dir* (the second path assuming the standard Quick Start location): bin/ttenv quickstart/ttquickstartenv
TNS_ADMIN	Required if you use the tnsnames naming method	Specifies the directory where the tnsnames.ora file is located. This is also where TimesTen looks for a sqlnet.ora file.
TWO_TASK (UNIX) LOCAL (Windows)	Optional	You can use this, whichever is appropriate for your platform, instead of specifying the *dbname* argument in your OCI logon call. The setting consists of a valid TNS name or easy connect string. See "Connecting to a TimesTen database from OCI" on page 3-9 for more information.
NLS_LANG	Optional	See "Character sets" on page 3-3. Only the character set component is honored and it must indicate a character set supported by TimesTen. The language and territory values are ignored. This environment variable overrides the TimesTen default character set.
NLS_SORT	Optional	See "Additional globalization features" on page 3-4. The sort order must be a value supported by TimesTen. This overrides the TimesTen NLS_SORT general connection attribute.
NLS_LENGTH_SEMANTICS	Optional	See "Additional globalization features" on page 3-4. This overrides the TimesTen NLS_LENGTH_SEMANTICS general connection attribute.
NLS_NCHAR_CONV_EXCP	Optional	See "Additional globalization features" on page 3-4. This overrides the TimesTen NLS_NCHAR_CONV_EXCP general connection attribute.

> **Note:**   Refer to "NLS general connection attributes" in *Oracle TimesTen In-Memory Database Reference* for information about the NLS connection attributes mentioned in the table.

Compiling and linking OCI applications

No changes are required between Oracle Database and TimesTen for the steps to compile and link an OCI application.

OCI programs that use the Oracle Client 11.2.0.2 library do not have to be recompiled or relinked to be executed with TimesTen.

Connecting to a TimesTen database from OCI

TimesTen OCI uses the Oracle Instant Client to connect to the TimesTen database. You can connect to the database through either the `tnsnames` or the *easy connect* naming method, similarly to how you would connect to an Oracle database through those methods.

This section covers the following topics:

- Using the tnsnames naming method to connect
- Using an easy connect string to connect
- Configuring whether to use tnsnames.ora or easy connect
- Connecting as an externally identified user in OCI

Refer to "Configuring Naming Methods" in *Oracle Database Net Services Administrator's Guide* for additional information about `tnsnames`, easy connect, and the `tnsnames.ora` file.

> **Notes:**
>
> - Although the `sqlnet` mechanism is used for a TimesTen OCI connection, the connection goes through the TimesTen ODBC driver, not the Oracle `sqlnet` driver.
>
> - Privilege to connect to the database must be explicitly granted, through the `CREATE SESSION` privilege, to every user other than the instance administrator who wants to connect to TimesTen. Refer to "Access control for connections" on page 2-6.

Using the tnsnames naming method to connect

TimesTen supports `tnsnames` syntax. You can use a TimesTen `tnsnames.ora` entry the same way you would use an Oracle `tnsnames.ora` entry.

The syntax of a TimesTen entry in `tnsnames.ora` is as follows:

```
tns_entry = (DESCRIPTION =
               (CONNECT_DATA =
                  (SERVICE_NAME = dsn)
                  (SERVER = timesten_direct | timesten_client)))
```

Where *tns_entry* is the arbitrary TNS name you assign to the entry. You can use this as the *dbname* argument in `OCILogon()`, `OCILogon2()`, and `OCIServerAttach()` calls.

`DESCRIPTION` and `CONNECT_DATA` are required as shown.

For `SERVICE_NAME`, *dsn* must be a TimesTen DSN that is configured in the `sys.odbc.ini` or user `odbc.ini` file that is visible to a user running your OCI application. On Windows, the DSN can be specified by using the ODBC Data Source Administrator. See "Managing TimesTen Databases" in *Oracle TimesTen In-Memory Database Operations Guide*.

For `SERVER`, `timesten_direct` specifies a direct connection to TimesTen or `timesten_client` specifies a client/server connection. If you choose `timesten_client`, the DSN must be configured as a client/server database.

As always, the host and port of the TimesTen server are determined from entries in the `sys.ttconnect.ini` file, according to the DSN. See "Working with the TimesTen Client and Server" in *Oracle TimesTen In-Memory Database Operations Guide*.

Here is a sample `tnsnames.ora` entry for a direct connection:

```
my_tnsname = (DESCRIPTION =
              (CONNECT_DATA =
                (SERVICE_NAME = my_dsn)
                (SERVER = timesten_direct)))
```

You can use the TNS name, `my_tnsname`, in either of the following ways:

- Specify "`my_tnsname`" for the *dbname* argument in your OCI logon call.

- Specify an empty string for *dbname* and set `TWO_TASK` or `LOCAL` to "`my_tnsname`".

For example:

```
OCILogon2(envhp, errhp, &svchp,
         (text *)"user1", (ub4)strlen("user1"),
         (text *)"pwd1", (ub4)strlen("pwd1"),
         (text *)"my_tnsname", (ub4)strlen((char*)"my_tnsname"), OCI_DEFAULT));
```

Refer to "Connect, Authorize, and Initialize Functions" in *Oracle Call Interface Programmer's Guide* for details about OCI logon calling sequences.

Or on a UNIX system, for example, you can set `TWO_TASK` to "`my_tnsname`" and use an OCI logon call with an empty string for *dbname*:

```
OCILogon2(envhp, errhp, &svchp,
         (text *)"user1", (ub4)strlen("user1"),
         (text *)"pwd1", (ub4)strlen("pwd1"),
         (text *)"", (ub4)0, OCI_DEFAULT));
```

Using an easy connect string to connect

TimesTen supports easy connect syntax, which enhances the Instant Client package by allowing connections to be made without configuring `tnsnames.ora`. An easy connect string has syntax similar to a URL, in the following format:

```
[//]host[:port]/service_name:server[/instance]
```

The initial double-slash is optional. A host name must be specified to satisfy easy connect syntax, but is otherwise ignored by TimesTen. The name "`localhost`" is typically used by convention. Any value specified for the port is also ignored. For client/server connections, the host and port of the TimesTen server are determined from entries in the `sys.ttconnect.ini` file, according to the TimesTen DSN.

Specify the DSN for *service_name*. Specify `timesten_client` or `timesten_direct`, as appropriate, for *server*.

TimesTen ignores the *instance* field and does not require that it be specified.

For example, the following easy connect string connects to a TimesTen server using the client/server libraries. Assume a DSN `ttclient` in the `sys.odbc.ini` file is resolved as a client/server data source and connects to the corresponding host and port specified in the `sys.ttconnect.ini` file:

```
"localhost/ttclient:timesten_client"
```

The following easy connect string is for a direct connection to TimesTen. Assume the DSN `ttdirect` is defined in `sys.odbc.ini`:

```
"localhost/ttdirect:timesten_direct"
```

You can use an easy connect string in either of the following ways:

- Specify it for the *dbname* argument in your OCI logon call.

- Specify an empty string for *dbname* and set `TWO_TASK` or `LOCAL` to the easy connect string, in quotes.

For example:

```
OCILogon2(envhp, errhp, &svchp,
        (text *)"user1", (ub4)strlen("user1"),
        (text *)"pwd1", (ub4)strlen("pwd1"),
        (text *)"localhost/ttclient:timesten_client",
        (ub4)strlen((char*)"localhost/ttclient:timesten_client"), OCI_DEFAULT));
```

Refer to "Connect, Authorize, and Initialize Functions" in *Oracle Call Interface Programmer's Guide* for details about OCI logon calling sequences.

Or on a UNIX system, for example, you can set `TWO_TASK` to `"localhost/ttclient:timesten_client"` and use an OCI logon call with an empty string for *dbname*:

```
OCILogon2(envhp, errhp, &svchp,
        (text *)"user1", (ub4)strlen("user1"),
        (text *)"pwd1", (ub4)strlen("pwd1"),
        (text *)"", (ub4)0, OCI_DEFAULT));
```

Configuring whether to use tnsnames.ora or easy connect

If a `sqlnet.ora` file is present, it specifies the naming methods that will be tried and the order in which they will be tried. The Instant Client will look for a `sqlnet.ora` file at the `TNS_ADMIN` location, if applicable. If `TNS_ADMIN` has not been set but `ORACLE_HOME` has been (such as if you had a previous Instant Client installation), the default `sqlnet.ora` location is the Oracle Database default location as noted in "Parameters for the sqlnet.ora File" in *Oracle Database Net Services Reference*.

If `sqlnet.ora` is found and does not indicate a particular naming method, you cannot use that method. If `sqlnet.ora` is not found, you can use either method.

In TimesTen, sample copies of `tnsnames.ora` and `sqlnet.ora` are in the `install_dir`/network/admin/samples directory. Here is the `sqlnet.ora` file that TimesTen provides, which supports both `tnsnames` and easy connect ("EZCONNECT"):

```
# To use ezconnect syntax or tnsnames, the following entries must be
# included in the sqlnet.ora configuration.
#
NAMES.DIRECTORY_PATH= (TNSNAMES, EZCONNECT)
```

With this file, TimesTen will first look for `tnsnames` syntax in your OCI logon calls. If it cannot find `tnsnames` syntax, it will look for easy connect syntax.

Connecting as an externally identified user in OCI

You can connect through OCI as an externally identified user (external user) by specifying the user name in brackets, such as "`[myadmin]`", and the password as an empty string, "".

In particular, this is useful in connecting as the instance administrator, which in TimesTen is always an external user.

Adapting an earlier example:

```
OCILogon2(envhp, errhp, &svchp,
          (text *)"[myadmin]", (ub4)strlen("[myadmin]"),
          (text *)"", (ub4)strlen(""),
          (text *)"my_tnsname", (ub4)strlen((char*)"my_tnsname"), OCI_DEFAULT));
```

This functionality uses OCI proxy syntax. You can refer to the discussion of client access through a proxy in *Oracle Call Interface Programmer's Guide*.

Error reporting

Errors under TimesTen OCI applications return Oracle Database error codes. TimesTen attempts to report the same error code as Oracle Database would under similar conditions. The error messages may come from either the TimesTen catalog or the Oracle Database catalog. Some error messages may indicate the accompanying TimesTen error code if appropriate.

Fatal errors are those that make the database inaccessible until after error recovery. When a fatal error occurs, all database connections are required to disconnect in order to avoid out-of-memory conditions. No further operations may complete. Shared memory from the old TimesTen instance will not be freed until all active connections at the time of the error have disconnected.

Fatal errors in OCI are indicated by the Oracle Database error code ORA-03135 or ORA-00600. Error handling for these errors should be different from standard error handling. In particular, the application error-handling code should have a disconnect from the database.

Signal handling and diagnostic framework considerations

The OCI diagnostic framework installs signal handlers that may impact any signal handling that you use in your application. You can disable OCI signal handling by setting DIAG_SIGHANDLER_ENABLED=FALSE in the sqlnet.ora file. Refer to "Fault Diagnosability in OCI" in *Oracle Call Interface Programmer's Guide* for information.

OCI demo programs

TimesTen ships OCI demo programs. They are in the quickstart/sample_code/oci directory. The README file in the directory explains how to compile and run the demos.

Refer to the Quick Start welcome page at *install_dir*/quickstart.html for information.

Additional features of TimesTen OCI

This section covers the following topics for developers using TimesTen OCI:

- TimesTen deferred prepare
- Parameter binding features in TimesTen OCI
- IMDB Cache with TimesTen OCI
- LOBs in TimesTen OCI

TimesTen deferred prepare

In OCI, a prepare call is expected to be a lightweight operation performed on the client. To allow TimesTen to be consistent with this expectation, and to avoid unwanted round trips between client and server, the TimesTen client library implementation of `SQLPrepare` performs what is referred to as a *deferred prepare*, where the request is not sent to the server until required. See "TimesTen deferred prepare" on page 2-10.

Parameter binding features in TimesTen OCI

This section discusses features relating to binding parameters into SQL or PL/SQL from an OCI application:

- Duplicate parameter bindings in TimesTen OCI

- Associative array bindings in TimesTen OCI

Duplicate parameter bindings in TimesTen OCI

"Binding duplicate parameters in SQL statements" on page 2-16 discusses the two supported modes for binding duplicate parameters in a SQL statement, either the Oracle mode or the traditional TimesTen mode. As in that section, consider the following query. Note that in TimesTen OCI, only the Oracle mode is supported.

```
SELECT * FROM employees
  WHERE employee_id < :a AND manager_id > :a AND salary < :b;
```

In OCI, as in the Oracle mode in general, two occurrences of parameter `a` are considered to be separate parameters. However, OCI allows both occurrences of `a` to be bound with a single call to `OCIBindByPos()`:

```
OCIBindByPos(..., 1, ...); /* both occurrences of :a */
OCIBindByPos(..., 3, ...); /* occurrence of :b */
```

Alternatively, OCI also allows the two occurrences of `a` to be bound separately:

```
OCIBindByPos(..., 1, ...); /* first occurrence of :a */
OCIBindByPos(..., 2, ...); /* second occurrence of :a */
OCIBindByPos(..., 3, ...); /* occurrence of :b */
```

Note that in both cases, parameter `b` is considered to be in position 3.

> **Note:** OCI also allows parameters to be bound by name, rather than by position, using `OCIBindByName()`.

Associative array bindings in TimesTen OCI

Associative arrays, formerly known as index-by tables or PL/SQL tables, are supported as `IN`, `OUT`, or `IN OUT` bind parameters in TimesTen PL/SQL, such as from an OCI application. This enables arrays of data to be passed efficiently between an application and the database.

An associative array is a set of key-value pairs. In TimesTen, for associative array binding (but not for use of associative arrays only within PL/SQL), the keys, or indexes, must be integers (`BINARY_INTEGER` or `PLS_INTEGER`). The values must be simple scalar values of the same data type. For example, there could be an array of department managers indexed by department numbers. Indexes are stored in sort order, not creation order.

You can declare an associative array type and then an associative array from PL/SQL as in the following example (note the INDEX BY):

```
declare
   TYPE VARCHARARRTYP IS TABLE OF VARCHAR2(30) INDEX BY BINARY_INTEGER;
   x VARCHARARRTYP;
   ...
```

For Pro*C/C++, see "Associative array bindings in TimesTen Pro*C/C++" on page 4-9.

For related information, see "Using associative array binds from applications" in *Oracle TimesTen In-Memory Database PL/SQL Developer's Guide*.

> **Notes:** Note the following restrictions in TimesTen:
>
> - The following types are not supported in binding associative arrays: LOBs, REF CURSORs, TIMESTAMP, ROWID.
>
> - Associative array binding is not allowed in passthrough statements.
>
> - General bulk binding of arrays is not supported in TimesTen OCI. Varrays and nested tables are not supported as bind parameters.

TimesTen supports associative array binds in OCI by supporting the maxarr_len and *curelep parameters of the OCIBindByName() and OCIBindByPos() functions. These parameters are used to indicate that the binding is for an associative array.

The complete calling sequences for those functions are as follows:

```
sword OCIBindByName ( OCIStmt *stmtp,
                      OCIBind **bindpp,
                      OCIError *errhp,
                      const OraText *placeholder,
                      sb4 placeh_len,
                      void *valuep,
                      sb4 value_sz,
                      ub2 dty,
                      void *indp,
                      ub2 *alenp,
                      ub2 *rcodep,
                      ub4 maxarr_len,
                      ub4 *curelep,
                      ub4 mode );

sword OCIBindByPos ( OCIStmt *stmtp,
                     OCIBind **bindpp,
                     OCIError *errhp,
                     ub4 position,
                     void *valuep,
                     sb4 value_sz,
                     ub2 dty,
                     void *indp,
                     ub2 *alenp,
                     ub2 *rcodep,
                     ub4 maxarr_len,
                     ub4 *curelep,
                     ub4 mode );
```

The `maxarr_len` and `*curelep` parameters are used as follows when you bind an associative array. (They should be set to 0 if you are not binding an associative array.)

- `maxarr_len`: This is an input parameter indicating the maximum array length. This is the maximum number of elements that the associative array can accommodate.

- `*curelep`: This is an input/output parameter indicating the current array length. It is a pointer to the actual number of elements in the associative array before and after statement execution.

For additional information about these functions, see "OCIBindByName()" and "OCIBindByPos()" in *Oracle Call Interface Programmer's Guide*.

> **Note:** In TimesTen, the `OCIBindDynamic()` function and the `OCI_DATA_AT_EXEC` mode setting for `OCIBindByName()` and `OCIBindByPos()` are not supported. (In Oracle Database, `OCIBindDynamic()` can be used to register user-defined callback functions to provide or receive data in "at exec" mode to set up additional bind attributes at execution time.)

In Example 3–1, an OCI application binds an integer array and a character array to corresponding `OUT` associative arrays in a PL/SQL procedure.

Example 3–1   Binding to an associative array from OCI

Assume the following SQL setup.

```
DROP TABLE FOO;

CREATE TABLE FOO (CNUM INTEGER,
                  CVC2 VARCHAR2(20));

INSERT INTO FOO VALUES ( null,
     'VARCHAR  1');
INSERT INTO FOO VALUES (-102,
     null);
INSERT INTO FOO VALUES ( 103,
     'VARCHAR  3');
INSERT INTO FOO VALUES (-104,
     'VARCHAR  4');
INSERT INTO FOO VALUES ( 105,
     'VARCHAR  5');
INSERT INTO FOO VALUES ( 106,
     'VARCHAR  6');
INSERT INTO FOO VALUES ( 107,
     'VARCHAR  7');
INSERT INTO FOO VALUES ( 108,
     'VARCHAR  8');

COMMIT;
```

Assume the following PL/SQL package definition. This has the `INTEGER` associative array type `NUMARRTYP` and the `VARCHAR2` associative array type `VCHARRTYP`, used for output associative arrays `c1` and `c2`, respectively, in the definition of procedure `P1`.

```
CREATE OR REPLACE PACKAGE PKG1 AS
  TYPE NUMARRTYP IS TABLE OF INTEGER INDEX BY BINARY_INTEGER;
  TYPE VCHARRTYP IS TABLE OF VARCHAR2(20) INDEX BY BINARY_INTEGER;
```

```
      PROCEDURE P1(c1 OUT NUMARRTYP,c2 OUT VCHARRTYP);

END PKG1;
/

CREATE OR REPLACE PACKAGE BODY PKG1 AS

  CURSOR CUR1 IS SELECT CNUM, CVC2 FROM FOO;

  PROCEDURE P1(c1 OUT NUMARRTYP,c2 OUT VCHARRTYP) IS
  BEGIN
    IF NOT CUR1%ISOPEN  THEN
      OPEN CUR1;
    END IF;
    FOR i IN 1..8 LOOP
      FETCH CUR1 INTO c1(i), c2(i);
      IF CUR1%NOTFOUND THEN
        CLOSE CUR1;
        EXIT;
      END IF;
    END LOOP;
  END P1;

END PKG1;
```

The following OCI program calls `PKG1.P1`, binds arrays to the `P1` output associative arrays, and prints the contents of those associative arrays. Note in particular the `OCIBindByName()` function calls to do the binding.

```

IMDB Cache with TimesTen OCI

This section discusses TimesTen OCI features related using the IMDB Cache:

- Specifying the Oracle Database password in OCI for IMDB Cache
- Determining the number of cache groups affected by an action

Specifying the Oracle Database password in OCI for IMDB Cache

To use IMDB Cache, there must be a cache user in the TimesTen database with the
same name as an Oracle Database user who can select from and update the cached
Oracle Database tables. This Oracle Database user, for example, can be the cache
administration user or a schema user. The password of the TimesTen cache user can be
different from the password of the Oracle Database user with the same name. See
"Setting Up a Caching Infrastructure" in *Oracle In-Memory Database Cache User's Guide*
for details.

For use of OCI with the IMDB Cache, TimesTen allows you to pass the Oracle
Database user's password through OCI by appending it to the password field in an
OCILogon() or OCILogon2() call when you log in to TimesTen. Use the attribute
OraclePWD in the connect string, such as in the following example:

```
text *cacheuser = (text *)"cacheuser1";
text *cachepwds = (text *)"ttpwd;OraclePWD=orclpwd";
text *ttdbname = (text *)"tt_tnsname";
....
OCILogon2(envhp, errhp, &svchp,
       (text *)cacheuser, (ub4)strlen(cacheuser),
       (text *)cachepwds, (ub4)strlen(cachepwds),
       (text *)ttdbname, (ub4)strlen(ttdbname), OCI_DEFAULT));
```

You must always specify OraclePWD, even if the Oracle Database user's password is
the same as the TimesTen user's password.

Note the following for the example:

- The name of the TimesTen cache user, as well as the name of the Oracle Database
  user who can access the cached Oracle Database tables, is cacheuser1.

- The password of the TimesTen cache user is ttpwd.

- The password of the Oracle Database user is orclpwd.

- The TNS name of the TimesTen database being connected to is tt_tnsname.

The Oracle database is specified through the TimesTen OracleNetServiceName general
connection attribute in the sys.odbc.ini or user odbc.ini file.

Alternatively, instead of using a TNS name, you could use easy connect syntax or the `TWO_TASK` or `LOCAL` environment variable, as discussed in preceding sections.

Determining the number of cache groups affected by an action

In TimesTen OCI, following the execution of a `FLUSH CACHE GROUP`, `LOAD CACHE GROUP`, `REFRESH CACHE GROUP`, or `UNLOAD CACHE GROUP` statement, the OCI Function `OCIAttrGet()` with the `OCI_ATTR_ROW_COUNT` argument returns the number of cache instances that were flushed, loaded, refreshed, or unloaded.

For related information, see "Determining the number of cache instances affected by an operation" in the *Oracle In-Memory Database Cache User's Guide*.

LOBs in TimesTen OCI

TimesTen supports LOBs (large objects). This includes CLOBs (character LOBs), NCLOBs (national character LOBs), and BLOBs (binary LOBs).

See "Working with LOBs" on page 2-23. That section is ODBC-oriented but also provides some general overview of LOBs, differences between TimesTen and Oracle Database LOBs, and LOB programming interfaces.

This section focuses on LOB locators, temporary LOBs, and OCI LOB APIs and features.

See "LOB data types" in *Oracle TimesTen In-Memory Database SQL Reference* for additional information about LOBs in TimesTen.

For complete information about LOBs and how to use them in OCI, refer to "LOB and BFILE Operations" in *Oracle Call Interface Programmer's Guide*, keeping in mind that TimesTen does not support BFILEs, SecureFiles, array reads and writes for LOBs, or callback functions for LOBs.

The following topics are covered here for OCI:

- LOB locators in OCI
- Temporary LOBs in OCI
- Differences between TimesTen LOBs and Oracle Database LOBs in OCI
- Using the LOB simple data interface in OCI
- Using the LOB locator interface in OCI
- OCI client-side buffering
- LOB prefetching in OCI
- Passthrough LOBs in OCI

> **Note:** The LOB piecewise data interface is not applicable to OCI applications in TimesTen. (You can, however, manipulate LOB data in pieces through features of the LOB locator interface.)

LOB locators in OCI

OCI provides the LOB locator interface, where a LOB consists of a LOB locator and a LOB value. The locator acts as a handle to the value. When an application selects a LOB from the database, it receives a locator. When it updates the LOB, it does so through the locator. And when it passes a LOB as a parameter, it is passing the locator, not the actual value. See "Using the LOB locator interface in OCI" on page 3-22. (Note

that in OCI it is also possible to use the simple data interface, which does not involve a locator. See "Using the LOB simple data interface in OCI" on page 3-21.)

To update a LOB, your transaction must have an exclusive lock on the row containing the LOB. You can accomplish this by selecting the LOB with a `SELECT ... FOR UPDATE` statement. This results in a writable locator. With a simple `SELECT` statement, the locator is read-only. Read-only and writable locators behave as follows:

- A read-only locator is *read consistent*, meaning that throughout its lifetime, it sees only the contents of the LOB as of the time it was selected. Note that this would include any uncommitted updates made to the LOB within the same transaction prior to when the LOB was selected.

- A writable locator is updated with the latest data from the database each time a write is made through the locator. So each write is made to the most current data of the LOB, including updates that have been made through other locators.

The following example details behavior for two writable locators for the same LOB:

1. The LOB column contains "XY".

2. Select locator `L1` for update.

3. Select locator `L2` for update.

4. Write "Z" through `L1` at offset 1.

5. Read through locator `L1`. This would return "ZY".

6. Read through locator `L2`. This would return "XY", because `L2` remains read-consistent until it is used for a write.

7. Write "W" through `L2` at offset 2.

8. Read through locator `L2`. This would return "ZW". Prior to the write in the preceding step, the locator was updated with the latest data ("ZY").

Temporary LOBs in OCI

A temporary LOB exists only within an application, and in TimesTen OCI has a lifetime no longer than the transaction in which it was created (as is the case with the lifetime of any LOB locator in TimesTen). You can think of a temporary LOB as a scratch area for LOB data.

An OCI application can instantiate a temporary LOB explicitly, for use within the application, through the appropriate API. (See "Using the LOB locator interface in OCI" on page 3-22.) A temporary LOB may also be created implicitly by TimesTen. For example, if a `SELECT` statement selects a LOB concatenated with an additional string of characters, TimesTen will implicitly create a temporary LOB to contain the concatenated data and an OCI application would receive a locator for the temporary LOB.

Temporary LOBs are stored in the TimesTen temporary data partition.

Differences between TimesTen LOBs and Oracle Database LOBs in OCI

A key difference between the TimesTen LOB implementation and the Oracle Database implementation is that in TimesTen, LOB locators do not remain valid past the end of the transaction. All LOB locators are invalidated after a commit or rollback, whether explicit or implicit. This includes after any DDL statement if TimesTen `DDLCommitBehavior` is set to 0 (the default), for Oracle Database behavior.

Also see "Differences between TimesTen LOBs and Oracle Database LOBs" on page 2-23.

Using the LOB simple data interface in OCI

The simple data interface enables applications to access LOB data by binding and defining, as with other scalar data types. The application can use a LOB type that is compatible with the corresponding variable type. Use `OCIStmtPrepare()` to prepare a statement. For binding parameters, use `OCIBindByName()` or `OCIBindByPos()`. For defining result columns, use `OCIDefineByPos()`.

For example, an OCI application can bind a CLOB parameter by calling `OCIBindByName()` with a data type of `SQLT_CHR`. Use `OCIStmtExecute()` to execute the statement. For an NCLOB parameter, use data type `SQLT_CHR` and set the OCI `csform` attribute (`OCI_ATTR_CHARSET_FORM`) to `SQLCS_NCHAR`. For a BLOB parameter, you can use data type `SQLT_BIN`.

Use of the simple data interface through OCI is shown in the following examples.

> **Note:** The simple data interface, through `OCIBindByName()`, `OCIBindByPos()`, or `OCIDefineByPos()`, limits bind sizes to 64 KB.

Example 3–2   Example table and variables

For examples that follow, assume the table and variables shown here.

```
person(ssn number, resume clob)

OCIEnv *envhp;
OCIServer *srvhp;
OCISvcCtx *svchp;
OCIError *errhp;
OCISession *authp;
OCIStmt *stmthp;

/* Bind Handles */
OCIBind *bndp1 = (OCIBind *) NULL;
OCIBind *bndp2 = (OCIBind *) NULL;

/* Define Handles */
OCIDefine *defnp1 = (OCIDefine *) NULL;
OCIDefine *defnp2 = (OCIDefine *) NULL;

#define DATA_SIZE 50
#define PIECE_SIZE 10
#define NPIECE (DATA_SIZE/PIECE_SIZE)

char col2[DATA_SIZE];
char col2Res[DATA_SIZE];
ub2 col2len = DATA_SIZE;
sb4 ssn = 123456;
...

text *ins_stmt = (text *)"INSERT INTO PERSON VALUES (:1, :2)";
text *sel_stmt = (text *)"SELECT * FROM PERSON_1 ORDER BY SSN";
...
```

Example 3–3   Insert LOB data using simple data interface

This example executes an `INSERT` statement using the simple data interface in OCI. It uses the table and variables from the preceding Example 3–2, including the `INSERT` statement defined through the variable `ins_stmt`.

```
for (i=0;i<DATA_SIZE;i++)
  col2[i] = 'A';

/* prepare SQL insert statement */
OCIStmtPrepare (stmthp, errhp, ins_stmt, strlen(ins_stmt), OCI_NTV_SYNTAX,
    OCI_DEFAULT);

/* bind parameters 1 and 2 using OCI_DEFAULT (not data-at-exec) */
OCIBindByPos (stmthp, &bndp1, errhp, 1, (dvoid *) &ssn, sizeof(ssn),
 SQLT_INT, 0, 0, 0, 0, 0, OCI_DEFAULT);
OCIBindByPos (stmthp, &bndp2, errhp, 2, (dvoid *) col2, col2len,
                           SQLT_CHR, 0, 0, 0, 0, 0, OCI_DEFAULT);

/* execute insert statement */
OCIStmtExecute (svchp, stmthp, errhp, 1, 0, 0, 0, OCI_DEFAULT);
```

Example 3–4   Select LOB data using simple data interface

This example executes a SELECT statement using the simple data interface in OCI. It uses the table and variables from the earlier Example 3–2, including the SELECT statement defined through the variable sel_stmt.

```
/* prepare select statement */
OCIStmtPrepare (stmthp, errhp, sel_stmt, strlen(sel_stmt), OCI_NTV_SYNTAX,
    OCI_DEFAULT);

/* define result columns 1 and 2 using OCI_DEFAULT (not data-at-exec) */
OCIDefineByPos (stmthp, &defnp1, errhp, 1, (dvoid*) &ssn, sizeof(ssn),
                            SQLT_INT, 0, 0, 0, OCI_DEFAULT);
OCIDefineByPos (stmthp, &defnp2, errhp, 2, (dvoid *) col2Res, sizeof(col2),
                            SQLT_CHR, 0, &col2len, 0, OCI_DEFAULT);

/* execute select statement */
OCIStmtExecute (svchp, stmthp, errhp, (ub4)1, (ub4)0, (OCISnapshot *) NULL,
                            (OCISnapshot *) NULL, OCI_DEFAULT));

/* col2Res should now have a DATA_SIZE sized string of 'A's. */
```

Using the LOB locator interface in OCI

You can use the OCI LOB locator interface to work with either a LOB from the database or a temporary LOB, either piece-by-piece or in whole chunks.

In order to use the LOB locator interface, the application must have a valid LOB locator. For a temporary LOB, this is obtained through the OCILobCreateTemporary() call, for explicitly created LOBs, or through a SQL statement that results in implicit creation of a temporary LOB (such as SELECT c1 || c2 FROM myclob). For a persistent LOB, use a SQL statement to obtain the LOB locator from the database. (There are examples later in this section.)

Bind types are SQLT_CLOB for CLOBs and SQLT_BLOB for BLOBs. For NCLOBs, use SQLT_CLOB and also set the OCI csform attribute (OCI_ATTR_CHARSET_FORM) to SQLCS_NCHAR.

Refer to "LOB Functions" in *Oracle Call Interface Programmer's Guide* for detailed information and additional examples for OCI LOB functions, noting that TimesTen does not support features specifically intended for BFILEs, SecureFiles, array reads and writes for LOBs, or callback functions for LOBs.

> **Important:** LOB manipulations through APIs that use LOB locators result in usage of TimesTen temporary space. Any significant number of such manipulations may necessitate a size increase for the TimesTen temporary data partition. See "TempSize" in *Oracle TimesTen In-Memory Database Reference*.

> **Notes:**
>
> - If an invalid LOB locator is assigned to another LOB locator using `OCILobLocatorAssign()`, the target of the assignment is also freed and marked as invalid.
>
> - `OCILobLocatorAssign()` can be used on a temporary LOB, but `OCILobAssign()` cannot.

Create a temporary LOB in OCI An OCI application can create a temporary LOB by using the `OCILobCreateTemporary()` function, which has an input/output parameter for the LOB locator, after first calling `OCIDescriptorAlloc()` to allocate the locator. When you are finished, use `OCIDescriptorFree()` to free the allocation for the locator and use `OCILobFreeTemporary()` to free the temporary LOB itself.

> **Important:** In TimesTen, creation of a temporary LOB will result in creation of a database transaction if one is not already in progress. To avoid error conditions, you must execute a commit or rollback to close the transaction.

In TimesTen, any duration supported by Oracle Database (`OCI_DURATION_SESSION`, `OCI_DURATION_TRANSACTION`, or `OCI_DURATION_CALL`) is permissible in the `OCILobCreateTemporary()` call; however, in TimesTen the lifetime of the temporary LOB itself will be no longer than the lifetime of the transaction.

Note that the lifetime of a temporary LOB can be shorter than the lifetime of the transaction in the following scenarios:

- If `OCI_DURATION_CALL` is specified

- If the application calls `OCILobFreeTemporary()` on the locator before the end of the transaction

- If the application calls `OCIDurationBegin()` to start a user-specified duration for the temporary LOB, then calls `OCIDurationEnd()` before the end of the transaction

Following are examples of some of the OCI LOB functions mentioned above. For details about the use of temporary LOBs and a complete example, see "Temporary LOB Support" in *Oracle Call Interface Programmer's Guide*.

```
if (OCIDescriptorAlloc((void*)envhp, (void **)&tblob,(ub4)OCI_DTYPE_LOB,
    (size_t)0, (void**)0))
{
   printf("failed in OCIDescriptor Alloc in select_and_createtemp \n");
   return OCI_ERROR;
}

...
```

```
if (OCILobCreateTemporary(svchp, errhp, tblob, (ub2)0, SQLCS_IMPLICIT,
    OCI_TEMP_BLOB, OCI_ATTR_NOCACHE, OCI_DURATION_TRANSACTION))
{
   (void) printf("FAILED: OCILobCreateTemporary() \n");
   return OCI_ERROR;
}

...

if(OCILobFreeTemporary(svchp,errhp,tblob))
{
   printf ("FAILED: OCILobFreeTemporary() call \n");
   return OCI_ERROR;
}
```

Access the locator of a persistent LOB in OCI An application typically accesses a LOB from the database by using a SQL statement to obtain or access a LOB locator, then passing the locator to an appropriate API function.

A LOB that has been created using the `EMPTY_CLOB()` or `EMPTY_BLOB()` SQL function has a valid locator, which an application can then use to insert data into the LOB by selecting it.

Assume the following table definition:

```
CREATE TABLE clobtable (x NUMBER, y DATE, z VARCHAR2(30), lobcol CLOB);
```

1. Prepare an `INSERT` statement. For example:

    ```
    INSERT INTO clobtable ( x, y, z, lobcol )
       VALUES ( 81, sysdate, 'giants', EMPTY_CLOB() )
       RETURNING lobcol INTO :a;
    ```

    Or, to initialize the LOB with some data:

    ```
    INSERT INTO clobtable ( x, y, z, lobcol )
       VALUES ( 81, sysdate, 'giants', 'The Giants finally won a World Series' )
       RETURNING lobcol INTO :a;
    ```

2. Bind the LOB locator to `:a` as shown.

3. Execute the statement. After execution, the locator will refer to the newly created LOB.

Then the application can use the LOB locator interface to read or write LOB data through the locator.

Alternatively, an application can use a `SELECT` statement to access the locator of an existing LOB.

Example 3–5 Select LOB locator using LOB locator interface

This example uses the following table:

```
person(ssn number, resume clob)
```

It selects the locator for the LOB column in the `PERSON` table.

```
text *ins_stmt = (text *)"INSERT INTO PERSON VALUES (:1, :2)";
text *sel_stmt = (text *)"SELECT * FROM PERSON WHERE SSN = 123456";
text *ins_empty = (text *)"INSERT INTO PERSON VALUES ( 1, EMPTY_CLOB())";

OCILobLocator *lobp;
```

```
ub4   amtp = DATA_SIZE;
ub4   remainder = DATA_SIZE;
ub4    nbytes = PIECE_SIZE;

/* Allocate lob locator */
OCIDescriptorAlloc (envhp, &lobp, OCI_DTYPE_LOB, 0, 0);

/* Insert an empty locator */
OCIStmtPrepare (stmhp, errhp, ins_empty, strlen(ins_empty), OCI_NTV_SYNTAX,
                            OCI_DEFAULT);
OCIStmtExecute (svchp, stmhp, errhp, 1, 0, 0, 0, OCI_DEFAULT);

/* Now select the locator */

OCIStmtPrepare (stmhp, errhp, sel_stmt, strlen(sel_stmt), OCI_NTV_SYNTAX,
                OCI_DEFAULT);

/* Call define for the lob column */
OCIDefineByPos (stmthp, &defnp2, errhp, 1, &lobp, 0 , SQLT_CLOB, 0, 0, 0,
                OCI_DEFAULT);

OCIStmtExecute (svchp, stmhp, errhp, 1, 0, 0, 0, OCI_DEFAULT);
```

Read and write LOB data using the OCI LOB locator interface An OCI application can use
`OCILobOpen()` and `OCILobClose()` to open and close a LOB. If you do not explicitly
open and close a LOB, it will be opened implicitly before a read or write and closed
implicitly at the end of the transaction.

An application can use `OCILobRead()` or `OCILobRead2()` to read LOB data,
`OCILobWrite()` or `OCILobWrite2()` to write LOB data, `OCILobWriteAppend()` or
`OCILobWriteAppend2()` to append LOB data, `OCILobErase()` or `OCILobErase2()` to
erase LOB data, and various other OCI functions to perform a variety of other actions.

For example, consider a CLOB with the content "Hello World!" You can overwrite and
append data by calling `OCILobWrite()` with an offset of 7 to write "I am a new string".
This would result in CLOB content being updated to "Hello I am a new string". Or, to
erase data from the original "Hello World!" CLOB, you can call `OCILobErase()` with an
offset of 7 and an amount (number of characters) of 5, for example, to update the
CLOB to "Hello   !" (six spaces).

All the OCI LOB locator interface functions are covered in detail in "LOB Functions" in
Oracle Call Interface Programmer's Guide.

> **Notes:**
>
> - Oracle Database emphasizes use of the "2" versions of the OCI read and write functions for LOBs (the non-"2" versions are deprecated as of the Oracle Database 11.2 release); however, currently in TimesTen there is no technical advantage in using `OCILobRead2()`, `OCILobWrite2()`, and `OCILobWriteAppend2()`, which are intended for LOBs larger than what TimesTen supports.
>
> - In using any of the LOB read or write functions, be aware that the callback function parameter must be set to `NULL` or 0, because TimesTen does not support callback functions for LOB manipulation.
>
> - Because TimesTen does not support binding arrays of LOBs, the `OCILobArrayRead()` and `OCILobArrayWrite()` functions are not supported.

Example 3–6   Write and read LOB data using LOB locator interface

This example shows how to write LOB data using the OCI LOB function `OCILobWrite()` and how to read data using `OCILobRead()`. It uses the table and variables from the preceding Example 3–5.

```
for (i=0;i<DATA_SIZE;i++)
  col2[i] = 'A';

/*************** Writing to the LOB ****************/

amt = DATA_SIZE;
offset = 1;

/* Write contents of col2 buffer into the LOB in a single chunk via locator lobp
*/
OCILobWrite (svchp, errhp, lobp, &amt, offset, col2, DATA_SIZE, OCI_ONE_PIECE,
                       0, 0, 0, SQLCS_IMPLICIT);

/*************** Reading from the LOB ****************/

/* Get the length of the LOB */
OCILobGetLength (svchp, errhp, lobp, &len);
amt = len;

/* Read the LOB data in col2Res in a single chunk */
OCILobRead (svchp, errhp, lobp, &amt, offset, col2Res, DATA_SIZE, 0, 0, 0,
                      SQLCS_IMPLICIT);
```

OCI client-side buffering

OCI provides a facility for client-side buffering on a per-LOB basis. It is enabled for a LOB by a call to `OCILobEnableBuffering()` and disabled by a call to `OCILobDisableBuffering()`.

Enabling buffering for a LOB locator creates a 512 KB write buffer. This size is not configurable. Data written by the application through the LOB locator is buffered. When possible, the client library will satisfy LOB read requests from the buffer as well. An application can flush the buffer by a call to `OCILobFlushBuffer()`. Note that buffers are not flushed automatically when they become full, and an attempt to write to the LOB through the locator when the buffer is full will result in an error.

The following restrictions apply when you use client-side buffering:

- Buffering is incompatible with the following functions: `OCILobAppend()`, `OCILobCopy()`, `OCILobCopy2()`, `OCILobErase()`, `OCILobGetLength()`, `OCILobTrim()`, `OCILobWriteAppend()`, and `OCILobWriteAppend2()`.

- An application can use `OCILobWrite()` or `OCILobWrite2()` only to append to the end of a LOB.

- LOB data becomes visible to SQL and PL/SQL (server-side) operations only after the application has flushed the buffer.

- When a LOB is selected while there are unflushed client-side writes in its buffer, the unflushed data is not included in the select.

LOB prefetching in OCI

To reduce round trips to the server in client/server connections, LOB data can be prefetched from the database and cached on the client side during fetch operations. LOB prefetching in OCI has the same functionality in TimesTen as in Oracle Database.

Configure LOB prefetching through the following OCI attributes. Note that size refers to bytes for BLOBs and to characters for CLOBs or NCLOBs.

- `OCI_ATTR_DEFAULT_LOBPREFETCH_SIZE`: Use this to enable prefetching and specify the default prefetch size. A value of 0 (default) disables prefetching.

- `OCI_ATTR_LOBPREFETCH_SIZE`: Set this attribute for a column define handle to specify the prefetch size for the particular LOB column.

- `OCI_ATTR_LOBPREFETCH_LENGTH`: This attribute can be set `TRUE` or `FALSE` (default) to prefetch LOB metadata such as LOB length and chunk size.

The `OCI_ATTR_DEFAULT_LOBPREFETCH_SIZE` and `OCI_ATTR_LOBPREFETCH_LENGTH` settings are independent of each other. You can use LOB data prefetching independently of LOB metadata prefetching.

Refer to "Prefetching of LOB Data, Length, and Chunk Size" in *Oracle Call Interface Programmer's Guide* for more information and an example.

> **Note:** The above attribute settings are ignored for TimesTen direct connections.

Passthrough LOBs in OCI

Passthrough LOBs (LOBs in Oracle Database accessed through TimesTen) are exposed as TimesTen LOBs and are supported by TimesTen in much the same way that any TimesTen LOB is supported, but note the following:

- You cannot use `OCILobCreateTemporary()` to create a passthrough LOB.

- In addition to copying from one TimesTen LOB to another TimesTen LOB—such as through `OCILobCopy()`, `OCILobCopy2()`, or `OCILobAppend()`—you can copy from a TimesTen LOB to a passthrough LOB, from a passthrough LOB to a TimesTen LOB, or from one passthrough LOB to another passthrough LOB. Any of these copies the LOB value to the target destination. For example, copying a passthrough LOB to a TimesTen LOB copies the LOB value into the TimesTen database.

  An attempt to copy a passthrough LOB to a TimesTen LOB when the passthrough LOB is larger than the TimesTen LOB size limit will result in an error.

- TimesTen LOB size limitations do not apply to storage of passthrough LOBs, but do apply to binding. Also, if a passthrough LOB is copied to a TimesTen LOB, the size limit applies to the copy.

- As with TimesTen local LOBs, a locator for a passthrough LOB does not remain valid past the end of the transaction.

Example 3–7   Copying between TimesTen LOBs and passthrough LOBs

The examples here highlight key functionality in copying between TimesTen LOBs and passthrough LOBs on Oracle Database. After the table and data setup, the first example uses `OCILobAppend()` to copy LOB data from Oracle Database to TimesTen and the second example uses `OCILobCopy()` to copy LOB data from TimesTen to Oracle Database. (Either call could be used in either case.) Then, for contrast, the third example uses an `UPDATE` statement to copy LOB data from Oracle Database to TimesTen and the fourth example uses an `INSERT` statement to copy LOB data from TimesTen to Oracle Database.

```
 /* Table and data setup */
call ttoptsetflag(''passthrough'', 3)';
DROP TABLE oratab';
CREATE TABLE oratab (i INT, c CLOB)';
INSERT INTO oratab VALUES (1, ''Copy from Oracle to TimesTen'')';
INSERT INTO oratab VALUES (2, EMPTY_CLOB())';
COMMIT;

call ttoptsetflag(''passthrough'', 0)';
DROP TABLE tttab';
CREATE TABLE tttab (i INT, c CLOB)';
INSERT INTO tttab VALUES (1, ''Copy from TimesTen to Oracle'')';
INSERT INTO tttab VALUES (2, EMPTY_CLOB())';
INSERT INTO tttab VALUES (3, NULL)';
COMMIT;
/* Table and data setup end */

/*
 * Below are four OCI pseudocode examples, for copying LOBs between
 * TimesTen and Oracle using OCI API and INSERT/UPDATE statements.
 */

/* Init OCI Env */

/* Set the passthrough level to 1 */
OCIStmtPrepare (..., "call ttoptsetflag(''passthrough'', 1)'", ...);
OCIStmtExecute (...);

/*
 * 1. Copy a passthrough LOB on Oracle to a TimesTen LOB
 */

/* Select a passthrough locator on Oracle */
OCIStmtPrepare (..., "SELECT c FROM oratab WHERE i = 1", ...);
OCIDefineByPos (..., (dvoid *)&ora_loc_1, 0 , SQLT_CLOB, ...);
OCIStmtExecute (...);

/* Select a locator on TimesTen for update */
OCIStmtPrepare (..., "SELECT c FROM tttab WHERE i = 2 FOR UPDATE", ...);
OCIDefineByPos (..., (dvoid *)&tt_loc_2, 0 , SQLT_CLOB, ...);
OCIStmtExecute (...);
```

```
                   /* Copy a passthrough LOB on Oracle to a TimesTen LOB */
                   OCILobAppend(..., tt_loc_2, ora_loc_1);

                   /*
                    * 2. Copy a TimesTen LOB to a passthrough LOB on Oracle
                    */

                   /* Select a passthrough locator on Oracle for update */
                   OCIStmtPrepare (..., "SELECT c FROM oratab WHERE i = 2 FOR UPDATE", ...);
                   OCIDefineByPos (..., (dvoid *)&ora_loc_2, 0 , SQLT_CLOB, ...);
                   OCIStmtExecute (...);

                   /* Select a locator on TimesTen */
                   OCIStmtPrepare (..., "SELECT c FROM tttab WHERE i = 1", ...);
                   OCIDefineByPos (..., (dvoid *)&tt_loc_1, 0 , SQLT_CLOB, ...);
                   OCIStmtExecute (...);

                   /* Copy a passthrough LOB on Oracle to a TimesTen LOB */
                   OCILobCopy(..., ora_loc_2, tt_loc_1, 28, 1, 1);

                   /*
                    * 3. UPDATE a TimesTen LOB with a passthrough LOB on Oracle
                    */

                   /* A passthrough LOB, (selected above in case 1) is bound to an UPDATE statement
                    * on TimesTen table */
                   OCIStmtPrepare (..., "UPDATE tttab SET c = :1 WHERE i = 3", ...);
                   OCIBindByPos (..., (dvoid *)&ora_loc_1, 0 , SQLT_CLOB, ...);
                   OCIStmtExecute (...);

                   /*
                    * 4. INSERT a passthrough table on Oracle with a TimesTen LOB
                    */

                   /* A TimesTen LOB, (selected above in case 2) is bound to an INSERT statement
                    * on a passthough table on Oracle */
                   OCIStmtPrepare (..., "INSERT INTO oratab VALUES (3, :1)", ...);
                   OCIBindByPos (..., (dvoid *)&tt_loc_1, 0 , SQLT_CLOB, ...);
                   OCIStmtExecute (...);

                   OCITransCommit (...);

                   /* Cleanup OCI Env */
```

TimesTen OCI support reference

This is a reference section for TimesTen support of OCI features, covering the following areas:

- Supported OCI calls
- Supported handles and attributes
- Supported descriptors
- Supported SQL data types
- Supported parameter attributes

Supported OCI calls

Table 3–2 lists TimesTen support for OCI calls that are documented for Oracle Database release 11.2.0.2.

Some groups of calls are represented with an asterisk in the name. For example, the calls related to Advanced Queuing, which TimesTen does not support, have names that start with `OCIAQ` and are represented in the table as `OCIAQ*()`. OCI date functions, which TimesTen does support, are designated by `OCIDate*()`.

Table 3–2   TimesTen OCI supported calls

OCI call	Supported	Notes
`OCIAQ*()`	No	TimesTen does not support Advanced Queuing.
`OCIAnyData*()`	No	TimesTen does not support Any Data.
`OCIAppCtxClearAll()`	Yes	
`OCIAppCtxSet()`	Yes	
`OCIArrayDescriptorAlloc()`	Yes	
`OCIArrayDescriptorFree()`	Yes	
`OCIAttrGet()`	Yes	TimesTen support includes special usage with cache groups. See "IMDB Cache with TimesTen OCI" on page 3-18.
`OCIAttrSet()`	Yes	
`OCIBinXml*()`	No	TimesTen does not support XML DB.
`OCIBindArrayOfStruct()`	Yes	This is supported for SQL statements but not PL/SQL.
`OCIBindByName()`	Yes	The following are unsupported values for the *mode* parameter: ■ `OCI_DATA_AT_EXEC` ■ `OCI_IOV`
`OCIBindByPos()`	Yes	The following are unsupported values for the *mode* parameter: ■ `OCI_DATA_AT_EXEC` ■ `OCI_IOV`
`OCIBindDynamic()`	No	
`OCIBindObject()`	No	TimesTen does not support user-defined objects.
`OCIBreak()`	No	
`OCICache*()`	No	TimesTen does not support user-defined objects.
`OCICharSetConversionIsReplacementUsed()`	Yes	
`OCICharSetToUnicode()`	Yes	
`OCIClientVersion()`	Yes	
`OCIColl*()`	No	TimesTen does not support collections.
`OCIConnectionPoolCreate()`	No	
`OCIConnectionPoolDestroy()`	No	

Table 3–2   (Cont.) TimesTen OCI supported calls

OCI call	Supported	Notes
`OCIContext*()`	No	TimesTen does not support Data Cartridge.
`OCIDBShutdown()`	No	
`OCIDBStartup()`	No	
`OCIDate*()`	Yes	See Table 3–4 on page 3-37 for information about descriptor support.
`OCIDefineArrayOfStruct()`	Yes	This is supported for SQL statements but not PL/SQL.
`OCIDefineByPos()`	Yes	The following are unsupported values for the *mode* parameter: ■ `OCI_DATA_AT_EXEC` ■ `OCI_IOV`
`OCIDefineDynamic()`	No	
`OCIDefineObject()`	No	
`OCIDescribeAny()`	Yes	PL/SQL objects are not supported. Describing objects is supported only by name. The following are unsupported values for the *objptr_typ* parameter: ■ `OCI_OTYPE_REF` ■ `OCI_OTYPE_PTR` The following are unsupported values for the *objtyp* parameter: ■ `OCI_PTYPE_PKG` ■ `OCI_PTYPE_FUNC` ■ `OCI_PTYPE_PROC` ■ `OCI_PTYPE_SYN` ■ `OCI_PTYPE_TYPE` When you use the setting `OCI_PTYPE_DATABASE` for the *objtyp* parameter, use the predetermined name `$TT_DB_NAME$` as the database name for the **objptr* parameter.
`OCIDescriptorAlloc()`	Yes	
`OCIDescriptorFree()`	Yes	
`OCIDirPath*()`	No	TimesTen does not support Direct Path Loading.
`OCIDurationBegin()`	Yes	Supported for LOBs. Regardless of the duration setting, the duration cannot exceed the lifetime of the transaction.
`OCIDurationEnd()`	Yes	Supported for LOBs. Regardless of the duration setting, the duration cannot exceed the lifetime of the transaction.
`OCIDuration*()`	No	TimesTen does not support Data Cartridge.

Table 3–2   (Cont.) TimesTen OCI supported calls

OCI call	Supported	Notes
OCIEnvCreate()	Yes	The following are unsupported values for the *mode* parameter: ■ OCI_EVENTS ■ OCI_NEW_LENGTH_SEMANTICS ■ OCI_NCHAR_LITERAL_REPLACE_ON ■ OCI_NCHAR_LITERAL_REPLACE_OFF ■ OCI_NO_MUTEX (Instead use OCI_ENV_NO_MUTEX.)
OCIEnvInit()	Yes	The following are unsupported values for the *mode* parameter: ■ OCI_NO_MUTEX ■ OCI_ENV_NO_MUTEX **Note**: Use OCIEnvCreate() instead of OCIEnvInit(). OCIEnvInit() is supported for backward compatibility.
OCIEnvNlsCreate()	Yes	The following are unsupported values for the *mode* parameter: ■ OCI_EVENTS ■ OCI_NCHAR_LITERAL_REPLACE_ON ■ OCI_NCHAR_LITERAL_REPLACE_OFF ■ OCI_NO_MUTEX (Instead use OCI_ENV_NO_MUTEX.)
OCIErrorGet()	Yes	
OCIExtProc*()	No	TimesTen does not support Data Cartridge.
OCIExtract*()	No	TimesTen does not support Data Cartridge.
OCIFile*()	No	TimesTen does not support Data Cartridge.
OCIFormatInit()	No	TimesTen does not support Data Cartridge.
OCIFormatString()	No	TimesTen does not support Data Cartridge.
OCIFormatTerm()	No	TimesTen does not support Data Cartridge.
OCIHandleAlloc()	Yes	
OCIHandleFree()	Yes	
OCIInitialize()	Yes	The following are unsupported values for the *mode* parameter: ■ OCI_NO_MUTEX ■ OCI_ENV_NO_MUTEX **Note**: Use OCIEnvCreate() instead of OCIInitialize(). OCIInitialize() is supported for backward compatibility.
OCIInterval*()	Yes	See Table 3–4 on page 3-37 for information about descriptor support.
OCIIter*()	No	TimesTen does not support collections.
OCILdaToSvcCtx()	No	

Table 3–2 (Cont.) TimesTen OCI supported calls

OCI call	Supported	Notes
OCILob*()	Yes	TimesTen supports OCILob*() functions other than the following:
		■ Functions specifically intended for array reads and writes
		■ Functions specifically intended for BFILEs
		■ Functions specifically intended for SecureFiles
		Notes:
		■ Regardless of the duration setting in an OCILobCreateTemporary() call, the LOB lifetime will be no longer than the lifetime of the transaction.
		■ See "Read and write LOB data using the OCI LOB locator interface" on page 3-25 regarding OCILobRead2(), OCILobWrite2(), and OCILobWriteAppend2().
OCILogoff()	Yes	
OCILogon()	Yes	
OCILogon2()	Yes	OCI_DEFAULT is the only supported value for the *mode* parameter.
OCIMemory*()	No	TimesTen does not support Data Cartridge.
OCIMessage*()	No	TimesTen does not support Data Cartridge.
OCIMultiByte*()	Yes	
OCINls*()	Yes	
OCINumber*()	Yes	
OCIObject*()	No	TimesTen does not support user-defined objects.
OCIParamGet()	Yes	
OCIParamSet()	Yes	
OCIPasswordChange()	No	
OCIPing()	Yes	
OCIRaw*()	Yes	
OCIRef*()	No	
OCIReset()	No	
OCIRowidToChar()	Yes	
OCIServer*()	Yes	OCI_DEFAULT is the only supported value for the *mode* parameter of OCIServerAttach.
OCISessionBegin()	Yes	OCI_CRED_RDBMS is the only supported value for the *credt* parameter.
		OCI_DEFAULT is the only supported value for the *mode* parameter.
OCISessionEnd()	Yes	

Table 3–2   (Cont.) TimesTen OCI supported calls

OCI call	Supported	Notes
OCISessionGet()	Yes	TimesTen does not support switching between sessions.
OCISessionPoolCreate()	No	
OCISessionPoolDestroy()	No	
OCISessionRelease()	Yes	
OCISharedLibInit()	No	
OCIStmtExecute()	Yes	The following are unsupported values for the *mode* parameter: ■ OCI_BATCH_ERRORS ■ OCI_STMT_SCROLLABLE_READONLY **Note**: Using OCI_COMMIT_ON_SUCCESS results in improved performance, avoiding an extra round trip to the server to commit a transaction.
OCIStmtFetch()	Yes	
OCIStmtFetch2()	Yes	The only supported values for the *orientation* parameter are OCI_DEFAULT and OCI_FETCH_NEXT.
OCIStmtGetBindInfo()	Yes	
OCIStmtGetPieceInfo()	No	
OCIStmtPrepare()	Yes	The only supported value for the *language* parameter is OCI_NTV_SYNTAX.
OCIStmtPrepare2()	Yes	The only supported value for the *mode* parameter is OCI_DEFAULT. For statement caching, TimesTen supports the *key* argument to tag a statement for future calls to OCIStmtPrepare2() or OCIStmtRelease().
OCIStmtRelease()	Yes	The only supported value for the *mode* parameter is OCI_DEFAULT. For statement caching, TimesTen supports the *key* argument to tag a statement. This can be the key from OCIStmtPrepare2().
OCIStmtSetPieceInfo()	No	
OCIString*()	Yes	
OCISubscription*()	No	TimesTen does not support Advanced Queuing.
OCISvcCtxToLda()	No	
OCITable*()	No	
OCITerminate()	No	
OCIThread*()	Yes	
OCITransCommit()	Yes	The only supported value for the *mode* parameter is OCI_DEFAULT.
OCITransDetach()	No	
OCITransForget()	No	

Table 3–2   (Cont.) TimesTen OCI supported calls

OCI call	Supported	Notes
OCITransMultiPrepare()	No	
OCITransPrepare()	No	
OCITransRollback()	Yes	
OCITransStart()	No	
OCIType*()	No	
OCIUnicodeToCharSet()	Yes	
OCIUserCallbackGet()	Yes	
OCIUserCallbackRegister()	Yes	
OCIWideChar*()	Yes	
OCIXmlDbFreeXmlCtx()	No	TimesTen does not support XML DB.
OCIXmlDbInitXmlCtx()	No	TimesTen does not support XML DB.

Supported handles and attributes

Table 3–3 lists the handles and attributes that TimesTen OCI supports.

Table 3–3   TimesTen OCI supported handles and attributes

Handle	C object	Supported attributes
Environment	OCIEnv	OCI_ATTR_ENV_CHARSET_ID
		OCI_ATTR_ENV_NCHARSET_ID
		OCI_ATTR_ENV_UTF16
		OCI_ATTR_EVTCTX
		OCI_ATTR_OBJECT
Error	OCIError	OCI_ATTR_DML_ROW_OFFSET
Service context	OCISvcCtx	OCI_ATTR_ENV
		OCI_ATTR_IN_V8_MODE
		OCI_ATTR_SERVER
		OCI_ATTR_SESSION
		OCI_ATTR_TRANS

Table 3–3   (Cont.) TimesTen OCI supported handles and attributes

Handle	C object	Supported attributes
Statement	OCIStmt	OCI_ATTR_BIND_COUNT
		OCI_ATTR_CURRENT_POSITION
		OCI_ATTR_ENV
		OCI_ATTR_FETCH_ROWID
		OCI_ATTR_NUM_DML_ERRORS
		OCI_ATTR_PARAM_COUNT
		OCI_ATTR_PREFETCH_MEMORY
		OCI_ATTR_PREFETCH_ROWS
		OCI_ATTR_ROW_COUNT
		OCI_ATTR_ROWID
		OCI_ATTR_ROWS_FETCHED
		OCI_ATTR_SQLFNCODE
		OCI_ATTR_STATEMENT
		OCI_ATTR_STMT_TYPE
Bind	OCIBind	OCI_ATTR_CHARSET_FORM
		OCI_ATTR_CHARSET_ID
		OCI_ATTR_MAXCHAR_SIZE
		OCI_ATTR_MAXDATA_SIZE
Define	OCIDefine	OCI_ATTR_CHARSET_FORM
		OCI_ATTR_CHARSET_ID
		OCI_ATTR_MAXCHAR_SIZE
Describe	OCIDescribe	OCI_ATTR_PARAM
		OCI_ATTR_PARAM_COUNT
Server	OCIServer	OCI_ATTR_ENV
		OCI_ATTR_IN_V8_MODE
		OCI_ATTR_SERVER_GROUP
		OCI_ATTR_SERVER_STATUS
User session	OCISession	OCI_ATTR_CLIENT_IDENTIFER
		OCI_ATTR_CLIENT_INFO
		OCI_ATTR_CURRENT_SCHEMA
		OCI_ATTR_DRIVER_NAME
		OCI_ATTR_INITIAL_CLIENT_ROLES
		OCI_ATTR_MODULE
		OCI_ATTR_PROXY_CREDENTIALS
		OCI_ATTR_USERNAME
Authentication	OCIAuthInfo	Same as for user session handle
Transaction	OCITrans	OCI_ATTR_TRANS_NAME
		OCI_ATTR_TRANS_TIMEOUT
Thread	OCIThreadHandle	

Supported descriptors

Table 3–4 lists the descriptors that TimesTen OCI supports.

Table 3–4   TimesTen OCI supported descriptors

Descriptor	C object
Parameter (read-only)	`OCIParam`
`ROWID`	`OCIRowid`
`ANSI DATE`	`OCIDateTime`
`TIMESTAMP`	`OCIDateTime`
`TIMESTAMP WITH TIME ZONE`	`OCIDateTime`
`TIMESTAMP WITH LOCAL TIME ZONE`	`OCIDateTime`
`INTERVAL YEAR TO MONTH`	`OCIInterval`
`INTERVAL DAY TO SECOND`	`OCIInterval`
User callback	`OCIUcb`

Supported SQL data types

Table 3–5 lists the SQL data types that TimesTen OCI supports.

Table 3–5   TimesTen OCI supported SQL data types

SQL data type	Notes
`SQLT_AFC`	
`SQLT_AVC`	
`SQLT_BDOUBLE`	
`SQLT_BFLOAT`	
`SQLT_BIN`	
`SQLT_BLOB`	
`SQLT_CHR`	
`SQLT_CLOB`	To write to or read from an NCLOB, set the character set form (`csfrm`) parameter to `SQLCS_NCHAR` for applicable function calls.
`SQLT_DAT`	
`SQLT_DATE`	
`SQLT_FLT`	
`SQLT_IBDOUBLE`	
`SQLT_IBFLOAT`	
`SQLT_INT`	
`SQLT_INTERVAL_DS`	Not stored in TimesTen.
`SQLT_INTERVAL_YM`	Not stored in TimesTen.
`SQLT_LBI`	
`SQLT_LNG`	
`SQLT_LVB`	Truncated at 4 MB when stored in TimesTen.
`SQLT_LVC`	Truncated at 4 MB when stored in TimesTen.

Table 3–5   (Cont.) TimesTen OCI supported SQL data types

SQL data type	Notes
SQLT_NUM	
SQLT_ODT	
SQLT_RDD	Rowids are returned in Oracle Database format.
SQLT_RSET	Only one result set parameter is allowed for each statement.
SQLT_STR	
SQLT_TIME	
SQLT_TIME_TZ	Time zone is ignored when stored in TimesTen.
SQLT_TIMESTAMP	
SQLT_TIMESTAMP_LTZ	Time zone is ignored when stored in TimesTen.
SQLT_TIMESTAMP_TZ	Time zone is ignored when stored in TimesTen.
SQLT_UIN	
SQLT_VBI	
SQLT_VCS	
SQLT_VNU	
SQLT_VST	

Supported parameter attributes

Table 3–6 that follows lists supported parameter attributes.

Table 3–6   TimesTen OCI supported parameter attributes

Parameter	Supported attributes
All parameters	OCI_ATTR_NUM_PARAMS
	OCI_ATTR_OBJ_NAME
	OCI_ATTR_OBJ_SCHEMA
	OCI_ATTR_PTYPE
Table and view parameters	OCI_ATTR_NUM_COLS
	OCI_ATTR_LIST_COLUMNS
PL/SQL procedure and function parameters	OCI_ATTR_LIST_ARGUMENTS
PL/SQL subprogram parameters	OCI_ATTR_LIST_ARGUMENTS
	OCI_ATTR_NAME
PL/SQL package parameters	OCI_ATTR_LIST_SUBPROGRAMS
Sequence parameters	OCI_ATTR_OBJID
	OCI_ATTR_MIN
	OCI_ATTR_MAX
	OCI_ATTR_INCR
	OCI_ATTR_CACHE
	OCI_ATTR_ORDER
	OCI_ATTR_HW_MARK

Table 3–6   (Cont.) TimesTen OCI supported parameter attributes

Parameter	Supported attributes
Column parameters	OCI_ATTR_CHAR_USED
	OCI_ATTR_CHAR_SIZE
	OCI_ATTR_DATA_SIZE
	OCI_ATTR_DATA_TYPE
	OCI_ATTR_NAME
	OCI_ATTR_PRECISION
	OCI_ATTR_SCALE
	OCI_ATTR_IS_NULL
	OCI_ATTR_TYPE_NAME
	OCI_ATTR_SCHEMA_NAME
	OCI_ATTR_CHARSET_ID
	OCI_ATTR_CHARSET_FORM
Argument and result parameters	OCI_ATTR_NAME
	OCI_ATTR_POSITION
	OCI_ATTR_DATA_TYPE
	OCI_ATTR_DATA_SIZE
	OCI_ATTR_PRECISION
	OCI_ATTR_SCALE
	OCI_ATTR_LEVEL

TimesTen Support for Pro*C/C++

TimesTen and Oracle IMDB Cache support the Oracle Pro*C/C++ Precompiler for C and C++ applications. You can use the precompiler with embedded SQL and PL/SQL applications that access the TimesTen database.

This chapter provides an overview and TimesTen-specific information regarding Pro*C/C++, especially emphasizing differences between using Pro*C/C++ with TimesTen versus with Oracle Database. For complete information about Pro*C/C++, you can refer to *Pro*C/C++ Programmer's Guide* in the Oracle Database library.

Also note that Chapter 2, "Working with TimesTen Databases in ODBC", contains information that may be of general interest regarding TimesTen features.

This chapter includes the following topics:

- Overview of the Oracle Pro*C/C++ Precompiler
- Overview of TimesTen support for Pro*C/C++
- Getting started with TimesTen Pro*C/C++
- Additional features of TimesTen Pro*C/C++
- TimesTen Pro*C/C++ Precompiler options

Overview of the Oracle Pro*C/C++ Precompiler

The Oracle Pro*C/C++ Precompiler enables you to embed SQL statements or PL/SQL blocks directly into C or C++ code. Further, you can use your C or C++ program host variables in your embedded SQL or PL/SQL.

You use a precompilation step to convert the Pro*C/C++ source file into a C or C++ source file. The precompiler accepts the Pro*C/C++ file as input, translates embedded SQL statements into standard Oracle Database runtime library calls, and generates a modified source code file that you can then compile and link. Pro*C/C++ code is linked against the Oracle precompiler `SQLLIB` library, which is shipped with TimesTen as part of the Oracle Instant Client.

Overview of TimesTen support for Pro*C/C++

TimesTen support for the Oracle Pro*C/C++ Precompiler depends on TimesTen OCI. TimesTen OCI depends on the Oracle client library and the TimesTen ODBC libraries. See Figure 3–1 on page 3-3 to see where OCI and Pro*C/C++ fit in the TimesTen architecture.

This chapter contains information specific to using the Oracle Pro*C/C++ Precompiler with TimesTen. The syntax and usage of the Oracle Pro*C/C++ Precompiler with TimesTen is essentially the same as with Oracle Database.

The rest of this section includes the following topics.

- TimesTen OCI support
- Embedded SQL support and restrictions
- Semantic checking restrictions
- Embedded PL/SQL restrictions
- Transaction restrictions
- Connection restrictions
- Summary of unsupported or restricted executable commands and clauses
- The ttSrcScan utility

TimesTen OCI support

Because TimesTen support of the Oracle Pro*C/C++ Precompiler depends on TimesTen OCI support, restrictions for TimesTen OCI apply to Pro*C/C++ applications.

In addition, TimesTen does not support OCI calls that are related to functionality that does not exist in TimesTen.

For more information about TimesTen OCI support, see Chapter 3, "TimesTen Support for OCI." Much of the information there may apply to Pro*C/C++ applications as well.

Embedded SQL support and restrictions

The TimesTen Pro*C/C++ Precompiler does not support embedded SQL for functionality that TimesTen and IMDB Cache do not support. See "TimesTen restrictions and differences" on page 3-5.

TimesTen provides the following support for SQLLIB functions:

- SQLErrorGetText (sqlglmt) is supported.
- SQLRowidGet() is supported following only SELECT FOR UPDATE statements.

In addition, TimesTen support for the Oracle Pro*C/C++ Precompiler has the following restrictions:

- REGISTER CONNECT is not supported.
- Stored Java subprograms are not supported.

Semantic checking restrictions

TimesTen support for the Oracle Pro*C/C++ Precompiler does not provide semantic checking during precompilation. A SQLCHECK precompiler option setting that specifies semantic checking is permissible but has no effect.

It is important to be aware, however, that a setting of SEMANTICS results in a database connection even though precompilation semantic checking is not performed. Therefore, a setting of SEMANTICS requires the following during precompilation:

- The database must be running.

■ The USERID precompiler option must be set, either on the command line or in the pcscfg.cfg configuration file. You must provide the user name and password for an existing TimesTen user, and a TNS name that points to the database. In the following example, you will be prompted for the password:

```
USERID=user1@my_tnsname
```

Alternatively, you can enter USERID=user1/mypassword@my_tnsname, but for security reasons it is not advisable to specify a password on a command line or in a configuration file.

See "Connecting to a TimesTen database from Pro*C/C++" on page 4-6 for information about usage and syntax for TNS names.

See the next section, "Embedded PL/SQL restrictions", for related information about Pro*C/C++ programs that use PL/SQL.

Embedded PL/SQL restrictions

In TimesTen, if a Pro*C/C++ application contains PL/SQL blocks, then Pro*C/C++ acts as though the SQLCHECK setting is SEMANTICS. It is important to be aware that this results in a database connection even though precompilation semantic checking is not performed. Therefore, using PL/SQL in a Pro*C/C++ application requires the following during precompilation:

■ The database must be running.

■ The USERID precompiler option must be set, specifying an existing TimesTen user. See the preceding section, "Semantic checking restrictions", for details about setting this option.

Transaction restrictions

Regarding transactions, TimesTen support for the Oracle Pro*C/C++ Precompiler does not provide the following:

■ SAVEPOINT SQL statement

■ SET TRANSACTION SQL statement

  You can still have transactions with commit and rollback, just not the SET TRANSACTION SQL statement.

■ Fetch across commits

■ Distributed transactions

Connection restrictions

Regarding connections, TimesTen support for the Oracle Pro*C/C++ Precompiler does not provide the following:

■ ALTER AUTHORIZATION clause

■ Automatic connections to the database

■ Making connections to the database with SYSDBA or SYSOPER privilege, given that these privileges do not exist in TimesTen

■ Implicit connections (dblinks) to a TimesTen or Oracle Database

For information about supported connection syntax, see "Connecting to a TimesTen database from Pro*C/C++" on page 4-6.

Summary of unsupported or restricted executable commands and clauses

Given restrictions including those noted in the preceding sections, this section summarizes the Pro*C/C++ EXEC SQL executable commands, categories of commands, and command clauses that TimesTen does not support or supports only partially:

- ALTER AUTHORIZATION

- CACHE FREE ALL

- CALL

  This is supported only for calling PL/SQL. To call TimesTen built-in procedures, use dynamic SQL statements.

- Any "COLLECTION..." command

- COMMIT FORCE 'some text'

- COMMIT WORK COMMENT 'some text' RELEASE

  The COMMENT clause is not supported.

- CONNECT BY

- CONTEXT OBJECT OPTION GET

- CONTEXT OBJECT OPTION SET

- DECLARE CURSOR

  The WITH HOLD clause is not supported.

- DECLARE TABLE

  Only Oracle Database data types are supported.

- DECLARE TYPE

- EXPLAIN PLAN

- IN SYSDBA MODE

- IN SYSOPER MODE

- LOCK TABLE

- Any "OBJECT..." command

- PARTITION

- REGISTER CONNECT

- RETURN

- RETURNING

- SAVEPOINT

- SET DESCRIPTOR

  You cannot set CHARACTER_SET_NAME.

- SET TRANSACTION

- START WITH

- TO SAVEPOINT

The ttSrcScan utility

If you have an existing Pro*C/C++ program and want to see whether it uses Pro*C/C++ features that TimesTen does not support, you can use the `ttSrcScan` command line utility to scan your program for unsupported embedded SQL functions and types. This is a standalone utility that can be run without TimesTen or Oracle Database being installed and runs on any platform supported by TimesTen. It reads source code files as input and creates HTML and text files as output. If the utility finds unsupported items, they are logged and alternatives are suggested. You can find the `ttSrcScan` executable in the `quickstart/sample_util` directory in your TimesTen installation.

Specify an input file or directory for the program to be scanned and an output directory for the `ttSrcScan` reports. Other options are available as well. See the README file in the `sample_util` directory for information.

Getting started with TimesTen Pro*C/C++

This section covers the following topics for getting started with a Pro*C/C++ application for TimesTen:

- Environment and configuration for TimesTen Pro*C/C++
- Building a Pro*C/C++ application
- Connecting to a TimesTen database from Pro*C/C++
- Error reporting and handling
- Pro*C/C++ demo programs

Environment and configuration for TimesTen Pro*C/C++

The Pro*C/C++ system configuration file `pcscfg.cfg` contains the precompiler options for precompilation of your Pro*C/C++ source code. In TimesTen, you must use the version of this file that TimesTen provides. This will typically happen automatically if you ensure appropriate configuration for TimesTen by executing the TimesTen `ttenv` script. Also see "Environment variables for TimesTen OCI" on page 3-7 and "Setting the environment for development" on page 1-1.

> **Note:** To ensure proper generation of OCI and Pro*C/C++ programs to be run on TimesTen, do not set `ORACLE_HOME` (or unset it if it was set previously) for OCI and Pro*C/C++ compilations.

Building a Pro*C/C++ application

Before building a Pro*C/C++ application, you must set up your environment:

1. You can use the TimesTen OCI and Pro*C/C++ Makefiles provided with the Quick Start demos to implement appropriate environment settings. These are in the following locations (assuming the standard Quick Start location):

   install_dir/quickstart/sample_code/oci/
   install_dir/quickstart/sample_code/proc/

2. Confirm `LD_LIBRARY_PATH` or `PATH` is set so that the Oracle Instant Client directory precedes the Oracle Database libraries in the path. The path will be set properly if you use the *install_dir*/bin/ttenv script or quickstart/ttquickstartenv

script. See "Environment variables" in *Oracle TimesTen In-Memory Database Installation Guide* for information about environment variables and `ttenv`.

Then use steps such as the following to build a Pro*C/C++ application. The steps shown here present a basic example for a UNIX system and assume the program has no other includes (`#include`) or links to other libraries. The designation *instant_client* represents the directory where Oracle Instant Client is installed.

See the Quick Start Pro*C/C++ Makefile in the `quickstart/sample_code/proc` directory for complete, platform-specific examples.

1. Precompile the Pro*C/C++ source file by using the `proc` command from your system prompt. For example:

```
% proc iname=sample.pc
```

   The `proc` utility takes a `.pc` source file as input and produces a `.c` file.

2. Compile the resulting C code file. On Linux platforms, enter a command similar to the following:

```
% gcc -c sample.c -I(instant_client)/sdk/
```

3. Link the resulting object modules with modules in `SQLLIB`. For example:

```
% gcc -o sample sample.o -L(instant_client)/lib -lclntsh
```

Connecting to a TimesTen database from Pro*C/C++

This section provides information on connecting to TimesTen from a Pro*C/C++ application. Also see "Connecting to a TimesTen database from OCI" on page 3-9 for information about using the `tnsnames` naming method or easy connect naming method to connect to the database.

The following topics are covered here:

- Connection syntax and parameters
- Using tnsnames or easy connect
- Specifying the Oracle Database password in Pro*C/C++ for IMDB Cache
- Connecting as an externally identified user in Pro*C/C++

Note: A TimesTen connection cannot be inherited from a parent process. If a process opens a database connection before creating (forking) a child process, the child must not use the connection. In Pro*C/C++, to avoid having a child process inadvertently inherit a connection from its parent, use `EXEC SQL COMMIT RELEASE` in the parent before creating the child.

Connection syntax and parameters

TimesTen supports the following connection syntax:

```
EXEC SQL CONNECT{:user IDENTIFIED BY :pwd | :user_string}
  [[AT{dbname |:host_variable}]USING :connect_string];
```

The parameters are described in Table 4–1.

Table 4–1   Connection parameters

Parameter	Description
user	User name
pwd	Password
user_string	Alternative to separate *user* and *pwd* entries
	This is a user name and password separated by a slash, such as user1/pwd1. After an "@" sign, you can also have a database identifier, instead of using *dbname*, or a TNS name or easy connect string, instead of using *connect_string*. See examples in the next section, "Using tnsnames or easy connect".
dbname	Database identifier declared in a previous DECLARE DATABASE statement
host_variable	Variable whose value is a database identifier
connect_string	Valid TNS name or easy connect string for a TimesTen database

Using tnsnames or easy connect

Your EXEC SQL CONNECT syntax can be simplified if you use the Oracle tnsnames or easy connect method.

From Pro*C/C++, you can use a host variable to specify the user name, password, and a TNS name. For example:

```
EXEC SQL CONNECT :dbstring
```

Where dbstring is set to "user1/pwd1@my_tnsname".

Alternatively, the host variable could specify the user name, password, and an easy connect string. For example, dbstring could be set to "user1/pwd1@localhost/ttclient:timesten_client".

Or, if the TWO_TASK or LOCAL environment variable, as applicable for your operating system, is set to "my_tnsname" or "localhost/ttclient:timesten_client", you could connect as in the following example:

```
EXEC SQL CONNECT :user1 IDENTIFIED BY :pwd1
```

Specifying the Oracle Database password in Pro*C/C++ for IMDB Cache

To use IMDB Cache, there must be a cache user in the TimesTen database with the same name as an Oracle Database user who can select from and update the cached Oracle Database tables. This Oracle Database user, for example, can be the cache administration user or a schema user. The password of the TimesTen cache user can be different from the password of the Oracle Database user with the same name. See "Setting Up a Caching Infrastructure" in *Oracle In-Memory Database Cache User's Guide* for details.

For use of Pro*C/C++ with IMDB Cache, TimesTen allows you to pass the Oracle Database user's password through Pro*C/C++ by appending it to the password field in an EXEC SQL CONNECT call when you log in to TimesTen. Use the attribute OraclePWD in the connect string, such as in the following example:

```
text *cacheuser = (text *)"cacheuser1";
text *cachepwds = (text *)"ttpwd;OraclePWD=orclpwd";
text *dbname = (text *)"tt_tnsname";
....
EXEC SQL CONNECT :cacheuser IDENTIFIED BY :cachepwds AT :dbname
```

You must always specify `OraclePWD`, even if the Oracle Database user's password is the same as the TimesTen user's password. Furthermore, in the circumstance of specifying an Oracle Database password for IMDB Cache, you must use a form of `EXEC SQL CONNECT` that specifies the password as a separate host variable. In this example, `cacheuser1` is the name of the TimesTen cache user as well as the name of the Oracle Database user who can access the cached Oracle Database tables, `ttpwd` is the password of the TimesTen cache user, `orclpwd` is the password of the Oracle Database user, and `tt_tnsname` is the TNS name of the TimesTen database being connected to. The Oracle database is specified through the TimesTen `OracleNetServiceName` general connection attribute in the `sys.odbc.ini` or user `odbc.ini` file.

Alternatively, instead of using the `AT` clause with a TNS name, you could use the `TWO_TASK` or `LOCAL` environment variable, as discussed in "Connecting to a TimesTen database from OCI" on page 3-9.

Connecting as an externally identified user in Pro*C/C++

You can connect through Pro*C/C++ as an externally identified user (external user) by specifying the user name in brackets, such as "`[myadmin]`", and the password as an empty string, "".

In particular, this is useful in connecting as the instance administrator, which in TimesTen is always an external user.

Consider the following example.

```
text *instanceadmin = (text *)"[myadmin]";
text *instanceadminpwd = (text *)"";
text *dbname = (text *)"tt_tnsname";
....
EXEC SQL CONNECT :instanceadmin IDENTIFIED BY :instanceadminpwd AT :dbname
```

This functionality uses OCI proxy syntax. You can refer to the discussion of client access through a proxy in *Oracle Call Interface Programmer's Guide*.

Error reporting and handling

Be aware of the following regarding error conditions and error reporting:

- Errors under TimesTen Pro*C/C++ applications return Oracle Database error codes. TimesTen attempts to report the same error code as Oracle Database would under similar conditions. The error messages may come from either the TimesTen catalog or the Oracle Database catalog. Some error messages may indicate the accompanying TimesTen error code if appropriate. Pro*C/C++ applications that rely on parsing error codes should be checked.

- TimesTen supports the `WHENEVER SQLERROR` directive, to go to an error handler if an error occurs, and the `WHENEVER NOT FOUND` directive, to go to a handling section if a "no data found" condition occurs. TimesTen does *not* support the `WHENEVER SQLWARNING` directive.

  Examples:

  ```
  EXEC SQL WHENEVER NOT FOUND GOTO close_cursor;
  ...
  EXEC SQL WHENEVER SQLERROR GOTO error_handler;
  ```

Pro*C/C++ demo programs

TimesTen ships Pro*C/C++ demo programs. They are in the `quickstart/sample_code/proc` directory. The README file in the directory explains how to compile and run the demos.

Refer to the Quick Start welcome page at *install_dir*/`quickstart.html` for information.

Additional features of TimesTen Pro*C/C++

This section covers additional features you can use with Pro*C/C++ in TimesTen:

- Associative array bindings in TimesTen Pro*C/C++
- LOBs in TimesTen Pro*C/C++

Associative array bindings in TimesTen Pro*C/C++

As discussed in "Associative array bindings in TimesTen OCI" on page 3-13, associative arrays, formerly known as index-by tables or PL/SQL tables, are supported as `IN`, `OUT`, or `IN OUT` bind parameters in TimesTen PL/SQL. See that section for additional information and limitations.

You can pass associative arrays between PL/SQL blocks and Pro*C/C++ applications as well as OCI applications. They can be indexed by a PL/SQL variable of type `BINARY_INTEGER` or `PLS_INTEGER`.

Normally, the entire host array is passed to PL/SQL, but you can use the Pro*C/C++ `ARRAYLEN` statement to specify a smaller array dimension.

For more information, refer to "PL/SQL Tables", "Host Arrays", and "ARRAYLEN Statement" under "Embedded PL/SQL" in *Pro*C/C++ *Programmer's Guide*.

Example 4–1   Binding to an associative array from Pro*C/C++

This code excerpt shows the array `salary[]` being bound from Pro*C/C++ into the associative array `num_tab` in PL/SQL.

```
...
float salary[100];
/* populate the host array */
EXEC SQL EXECUTE
  DECLARE
    TYPE NumTabTyp IS TABLE OF REAL
                  INDEX BY BINARY_INTEGER;
    median_salary REAL;
    n BINARY_INTEGER;
...
  FUNCTION median (num_tab NumTabTyp, n INTEGER)
    RETURN REAL IS
  BEGIN
    -- compute median
  END;
  BEGIN
    n := 100;
    median_salary := median(:salary, n);
    ...
  END;
END-EXEC;
...
```

LOBs in TimesTen Pro*C/C++

TimesTen supports LOBs (large objects). This includes CLOBs (character LOBs), NCLOBs (national character LOBs), and BLOBs (binary LOBs).

See "Working with LOBs" on page 2-23. That section is ODBC-oriented but also provides a general overview of LOBs, differences between TimesTen and Oracle Database LOBs, and LOB programming interfaces. Also see "LOBs in TimesTen OCI" on page 3-19 for information about LOB locators, temporary LOBs, using the simple data interface or LOB locator interface in OCI, and additional OCI LOB features.

This section focuses on key Pro*C/C++ LOB features and TimesTen-specific support and restrictions.

See "LOB data types" in *Oracle TimesTen In-Memory Database SQL Reference* for additional information about LOBs in TimesTen.

For complete information about LOBs and how to use them in Pro*C/C++, refer to "LOBs" in *Pro*C/C++ Programmer's Guide*, keeping in mind that TimesTen does not support BFILEs, SecureFiles, array reads and writes for LOBs, or callback functions for LOBs. In particular, see "How to Use LOBs in Your Program" within that chapter.

The following topics are covered for Pro*C/C++:

- Using the LOB simple data interface in Pro*C/C++

- Using the LOB locator interface in Pro*C/C++

> **Important:** As indicated in the OCI chapter, in TimesTen a LOB used in an application does not remain valid past the end of the transaction.

> **Note:** The LOB piecewise data interface is not applicable to OCI or Pro*C/C++ applications in TimesTen. (You can, however, manipulate LOB data in pieces through features of the LOB locator interface.)

Using the LOB simple data interface in Pro*C/C++

The simple data interface enables applications to manipulate LOB data similarly to how they would manipulate other types of scalar data, such as by using `EXEC SQL INSERT` and `EXEC SQL SELECT`. The application can use a LOB type that is compatible with the corresponding variable type.

An application can use the `EMPTY_BLOB()` or `EMPTY_CLOB()` function, as appropriate, to initialize a persistent LOB. This is similar to using `ALLOCATE` in the LOB locator interface, discussed next. Consider the following tables:

```
EXEC SQL CREATE TABLE lob_table ( a_blob BLOB, a_clob CLOB );
...
EXEC SQL INSERT INTO lob_table (a_blob, a_clob)
                VALUES (EMPTY_BLOB(), EMPTY_CLOB());
...
EXEC SQL CREATE TABLE data_table
        ( name VARCHAR2(30), length NUMBER(10), bincol BLOB, charcol CLOB );
```

The following selects LOB data from `data_table` into `myblob` and `myclob`, then inserts the LOB data into `lob_table`.

```
...
OCIBlobLocator *myblob;
```

```
OCIClobLocator *myclob;
...
EXEC SQL SELECT bincol, charcol INTO :myblob, :myclob FROM data_table
                WHERE name = :key;
...
// Put data into lob_table.
...
EXEC SQL INSERT INTO lob_table (a_blob, a_clob) VALUES (:myblob, :myclob);
```

To use an NCLOB, declare the variable as follows:

```
OCIClobLocator CHARACTER SET IS NCHAR_CS *mynclob;
```

> **Note:** The simple data interface, through OCI or Pro*C/C++, limits bind sizes to 64 KB.

Using the LOB locator interface in Pro*C/C++

You can use the Pro*C/C++ LOB locator interface to work with either LOBs from the database or temporary LOBs, either piece-by-piece or in whole chunks.

Refer to "LOB Statements" in *Pro*C/C++ Programmer's Guide* for detailed information about Pro*C/C++ statements for LOBs, noting that TimesTen does not support features specifically intended for BFILEs, SecureFiles, array reads and writes for LOBs, or callback functions for LOBs.

Refer to the lobdemo1.pc example in "LOBs" in *Pro*C/C++ Programmer's Guide* for an end-to-end example.

Also see "Using the LOB locator interface in OCI" on page 3-22 for related information and usage notes.

> **Note:** If Pro*C/C++ syntax does not provide enough functionality to fully specify what you want to accomplish for any operation, you can use the corresponding OCI function as an alternative.

Create a temporary LOB in Pro*C/C++ A Pro*C/C++ application can create a temporary LOB by using the CREATE TEMPORARY embedded SQL feature, after first using the ALLOCATE feature to allocate the locator. Use FREE to free the allocation for the locator and FREE TEMPORARY to free the temporary LOB itself. This is shown below.

Also see "Create a temporary LOB in OCI" on page 3-23.

> **Important:** In TimesTen, creation of a temporary LOB will result in creation of a database transaction if one is not already in progress. To avoid error conditions, you must execute a commit or rollback to close the transaction.

```
OCIClobLocator *tempclob;
EXEC SQL ALLOCATE :tempclob;
EXEC SQL LOB CREATE TEMPORARY :tempclob;
...
// (Manipulate LOB as desired.)
...
EXEC SQL FREE TEMPORARY :tempclob;
```

```
EXEC SQL FREE :tempclob;
```

Alternatively, if you want to specify the LOB character set (here NCHAR), you can use the corresponding OCI function:

```
status = OCILobCreateTemporary(svc, err, tempclob, OCI_DEFAULT, SQLCS_NCHAR,
        OCI_TEMP_CLOB, TRUE, OCI_DURATION_TRANSACTION);
```

Access the locator of a persistent LOB in Pro*C/C++ An application typically accesses a LOB from the database by using a SQL statement to obtain a LOB locator, then passing the locator to an appropriate API function.

Also see "Access the locator of a persistent LOB in OCI" on page 3-24.

The following excerpts are from the previously mentioned lobdemo1.pc example in *Pro*C/C++ Programmer's Guide*. The example uses a CLOB license_txt and table license_table whose columns are social security number, name, and text summarizing driving offenses (a CLOB column).

```
OCIClobLocator *license_txt;
...
EXEC SQL ALLOCATE :license_txt;
...
EXEC SQL SELECT name, txt_summary INTO :name, :license_txt FROM license_table
               WHERE sss = :sss;
```

Read and write LOB data using the Pro*C/C++ LOB locator interface A Pro*C/C++ application can use LOB OPEN and LOB CLOSE to open and close a LOB, LOB READ to read LOB data, LOB WRITE or LOB WRITE APPEND to write or append LOB data, LOB DESCRIBE to obtain information about a LOB, and various other Pro*C/C++ features to perform a variety of other actions. All the Pro*C/C++ LOB locator interface features are covered in detail in "LOBs" in *Pro*C/C++ Programmer's Guide*.

To write data, use LOB WRITE ONE to write the data in a single chunk. TimesTen does not support LOB WRITE FIRST, LOB WRITE NEXT, or LOB WRITE LAST (features of the piecewise data interface).

Also see "Read and write LOB data using the OCI LOB locator interface" on page 3-25.

Here is an example of an EXEC SQL LOB READ statement:

```
EXEC SQL LOB READ :amt FROM :blob INTO :buffer;
```

Refer to "Read a File, WRITE a BLOB Example" in "LOBs" in *Pro*C/C++ Programmer's Guide* for additional information.

Here is an example of an EXEC SQL LOB WRITE statement (writing the LOB data in one chunk):

```
EXEC SQL LOB WRITE ONE :amt FROM :buffer INTO :blob;
```

Refer to "READ a BLOB, Write a File Example" in "LOBs" in *Pro*C/C++ Programmer's Guide* for additional information.

Here is an example of an EXEC SQL LOB WRITE APPEND statement:

```
EXEC SQL LOB WRITE APPEND :amt FROM :writebuf INTO :blob;
```

> **Note:** Opening a LOB is similar conceptually, but not technically, to opening a file. Opening a LOB is more like a hint regarding resources to be required.
>
> Be aware that a LOB being accessed by `OCILobRead()`, `OCILobWrite()`, or equivalent functionality is opened automatically as necessary.

Example 4–2   Write a LOB using Pro*C/C++ LOB locator interface

The following excerpt is from the previously mentioned `lobdemo1.pc` example in *Pro*C/C++ Programmer's Guide*.

```
...
OCIClobLocator *a_clob;
char *charbuf;
ub4 ClobLen, WriteAmt;
int CharLen = strlen(charbuf);
int NewCharbufLen = CharLen + DATELENGTH + 4;
varchar *NewCharbuf;
NewCharbuf = (varchar *)malloc(2 + NewCharbufLen);
NewCharbuf->arr[0] = '\n';
NewCharbuf->arr[1] = '\0';
strcat((char *)NewCharbuf->arr, charbuf);
NewCharbuf->arr[CharLen + 1] = '\0';
strcat((char *)NewCharbuf->arr, curdate);
NewCharbuf->len = NewCharbufLen;
EXEC SQL LOB DESCRIBE :a_clob GET LENGTH INTO :ClobLen;
WriteAmt = NewCharbufLen;
EXEC SQL LOB WRITE ONE :WriteAmt FROM :NewCharbuf WITH LENGTH :NewCharbufLen
                      INTO :a_clob;
...
```

Example 4–3   Write and append to a LOB using Pro*C/C++ LOB locator interface

This example, like the preceding one, uses `LOB WRITE ONE`. Then it also uses `LOB WRITE APPEND` to append additional data. It writes or appends to the BLOB in 1 K chunks up to `MAX_CHUNKS`.

```
...
 EXEC SQL select b into :blob from t where pk = 1 for update;
 EXEC SQL LOB OPEN :blob READ WRITE;

// Write/append to the BLOB
 for (i = 0; i < MAX_CHUNKS; i++) {
   if (i==0) { // FIRST CHUNK
     /*
     Write the first piece
     */
     EXEC SQL LOB WRITE ONE :amt FROM :writebuf INTO :blob;

   }
   else { // All Other Chunks
     /*
     At this point, APPEND all the next pieces
     */
     EXEC SQL LOB WRITE APPEND :amt FROM :writebuf INTO :blob ;
   }
   ...
 }
...
```

TimesTen Pro*C/C++ Precompiler options

This section discusses Pro*C/C++ Precompiler option support by TimesTen.

Precompiler option support

Table 4–2 describes TimesTen Pro*C/C++ Precompiler option support.

*Table 4–2   TimesTen Pro*C/C++ Precompiler option support*

Option	Notes
AUTO_CONNECT	Supported value: NO (default)
CHAR_MAP	Supported
CINCR	Not applicable Setting has no effect because TimesTen supports only CPOOL=NO.
CLOSE_ON_COMMIT	Supported value: YES The Oracle Database default value of NO is overridden by TimesTen.
CMAX	Not applicable Setting has no effect because TimesTen supports only CPOOL=NO.
CMIN	Not applicable Setting has no effect because TimesTen supports only CPOOL=NO.
CNOWAIT	Not applicable Setting has no effect because TimesTen supports only CPOOL=NO.
CODE	Supported
COMP_CHARSET	Supported
CONFIG	Supported
CPOOL	Supported value: NO (default)
CPP_SUFFIX	Supported
CTIMEOUT	Not applicable Setting has no effect because TimesTen supports only CPOOL=NO.
DB2_ARRAY	Supported
DBMS	Supported value: NATIVE (default)
DEF_SQLCODE	Supported
DEFINE	Supported
DURATION	Not applicable Setting has no effect because TimesTen does not support objects.
DYNAMIC	Supported
ERRORS	Supported
ERRTYPE	Not supported
EVENTS	Not applicable Both values allowed, but TimesTen OCI does not support Advanced Queuing.
FIPS	Supported

*Table 4–2   (Cont.) TimesTen Pro*C/C++ Precompiler option support*

Option	Notes
HEADER	Supported
HOLD_CURSOR	Supported
IMPLICIT_SVPT	Supported value: NO (default)
INAME	Supported
INCLUDE	Supported
INTYPE	Supported
LINES	Supported
LNAME	Supported
LTYPE	Supported
MAX_ROW_INSERT	Supported
MAXLITERAL	Supported
MAXOPENCURSORS	Supported
MODE	Supported
NATIVE_TYPES	Supported
NLS_CHAR	Supported
NLS_LOCAL	Supported value: NO (default)
OBJECTS	Not applicable Setting has no effect because TimesTen does not support objects.
ONAME	Supported
ORACA	Supported
OUTLINE	Not applicable All values are allowed, but TimesTen does not support Oracle Database optimization.
OUTLNPREFIX	Not applicable Both values are allowed, but TimesTen does not support Oracle Database optimization.
PAGELEN	Supported
PARSE	Supported
PREFETCH	Supported
RELEASE_CURSOR	Supported
RUNOUTLINE	Not applicable Both values (yes|no) are allowed but ignored.
SELECT_ERROR	Supported

*Table 4–2   (Cont.) TimesTen Pro*C/C++ Precompiler option support*

Option	Notes
SQLCHECK	Not applicable
	Any of the SQLCHECK settings is allowed, but TimesTen does not support semantic checking during precompilation.
	Whenever a Pro*C/C++ application uses PL/SQL, Pro*C/C++ acts as though the SQLCHECK setting is SEMANTICS.
	Important: A setting of SEMANTICS (or FULL, which is synonymous) always results in a connection to the database, even though precompilation semantic checking is not performed.
	See "Semantic checking restrictions" on page 4-2.
STMT_CACHE	Supported
SYS_INCLUDE	Supported
THREADS	Supported
TYPE_CODE	Supported
UNSAFE_NULL	Supported
USERID	Supported
UTF16_CHARSET	Supported value: NCHAR_CHARSET
VARCHAR	Supported
VERSION	Not applicable
	Setting has no effect because TimesTen does not support objects.

> **Note:** TimesTen does not support the default value for CLOSE_ON_COMMIT. TimesTen supports only CLOSE_ON_COMMIT=YES.

Setting precompiler options

You can set precompiler options in the following ways.

- At compile time, either in the configuration file `pcscfg.cfg` or on the Pro*C/C++ command line

  A setting on the command line takes precedence over a setting in the configuration file.

- At runtime through the EXEC ORACLE OPTION command

  A runtime setting takes precedence over a compile-time setting.

For example, the following shows portions of the configuration file that ships with TimesTen.

```
ltype=short
parse=full
close_on_commit=yes
...
```

The following command line would override the `ltype=short` setting from the configuration file:

```
% proc ltype=long ... iname=sample.pc
```

The following runtime command would override the `ltype=long` setting from the command line:

```
EXEC ORACLE OPTION LTYPE=NONE;
```

5

XLA and TimesTen Event Management

The Transaction Log API (XLA) is a set of C language functions that enable you to implement applications to perform the following:

■ Monitor TimesTen for changes to specified tables in a local database.

■ Receive real-time notification of these changes.

The primary purpose of XLA is as a high-performance, asynchronous alternative to triggers.

> **Note:** In the unlikely event that TimesTen replication solutions described in *Oracle TimesTen In-Memory Database Replication Guide* do not meet your needs, it is possible to use XLA functions to build a custom data replication solution.

This chapter includes the following topics:

■ XLA concepts

■ Writing an XLA event-handler application

■ Using XLA as a replication mechanism

■ Other XLA features

For a complete description of each XLA function, see Chapter 9, "XLA Reference".

XLA concepts

This section includes the following topics:

■ XLA basics

■ How XLA reads records from the transaction log

■ About XLA and materialized views

■ About XLA bookmarks

■ About XLA data types

■ Access control impact on XLA

■ XLA limitations

■ XLA demo

XLA functions mentioned here are documented in Chapter 9, "XLA Reference".

XLA basics

TimesTen XLA obtains update records directly from the transaction log buffer or transaction log files, so the records are available for as long as they are needed. The logging model also enables multiple readers to simultaneously read transaction log updates.

The `ttXlaPersistOpen` XLA function opens a connection to the database.

When initially created, TimesTen configures a transaction log handle for the same version as the TimesTen release to which the application is linked. You can also use the `ttXlaGetVersion` and `ttXlaSetVersion` XLA functions to interoperate with earlier XLA versions.

How XLA reads records from the transaction log

As applications modify a database, TimesTen generates transaction log records that describe the changes made to the data and other events such as transaction commits.

New transaction log records are always written to the end of the log buffer as they are generated.

Transaction log records are periodically flushed in batches from the log buffer in memory to transaction log files on disk. When XLA is initialized, the XLA application does not have to be concerned with which portions of the transaction log are on disk or in memory. Therefore, the term "transaction log" as used in this chapter refers to the "virtual" source of transaction update records, regardless of whether those records are physically located in memory or on disk.

Applications can use XLA to monitor the transaction log for changes to the database. XLA reads through the transaction log, filters the log records, and delivers to XLA applications a list of transaction records that contain the changes to the tables and columns of interest.

XLA sorts the records into discrete transactions. If multiple applications are updating the database simultaneously, transaction log records from the different applications will be interleaved in the transaction log.

XLA transparently extracts all transaction log records associated with a particular transaction and delivers them in a contiguous list to the application.

Only the records for committed transactions are returned. They are returned in the order in which their final commit record appears in the transaction log. XLA filters out records associated with changes to the database that have not yet been committed.

If a change is made but then rolled back, XLA does not deliver the records for the aborted transaction to the application.

Most of these basic XLA concepts are demonstrated in Example 5–1 that follows and summarized in the bulleted list following the example.

Consider the example transaction log illustrated in Figure 5–1.

Figure 5–1   Records extracted from the transaction log

Transaction Log

Oldest | ----------------- | CT₁ | BT₁ | CT₂ | BT₂ | AT₁ | AT₂ | BT₃ | AT₃ | CT₃ | ----------------- | Newest

XLA Application

| BT₂ | BT₃ | CT₁ | CT₂ | CT₃ |
Example 5–1   Reading transaction log records

In this example, the transaction log contains the following records:

CT1 - Application C updates row 1 of table W with value 7.7.
BT1 - Application B updates row 3 of table X with value 2.
CT2 - Application C updates row 9 of table W with value 5.6.
BT2 - Application B updates row 2 of table Y with value "XYZ".
AT1 - Application A updates row 1 of table Z with value 3.
AT2 - Application A updates row 3 of table Z with value 4.
BT3 - Application B commits its transaction.
AT3 - Application A rolls back its transaction.
CT3 - Application C commits its transaction.

An XLA application that is set up to detect changes to tables W, Y, and Z would see the following:

BT2 and BT3 - Update row 2 of table Y with value "XYZ" and commit.
CT1 - Update row 1 of table W with value 7.7.
CT2 and CT3 - Update row 9 of table W with value 5.6 and commit.

This example demonstrates the following:

- Transaction records of applications B and C all appear together.

- Although the records for application C begin to appear in the transaction log before those for application B, the commit for application B (BT3) appears in the transaction log before the commit for application C (CT3). As a result, the records for application B are returned to the XLA application ahead of those for application C.

- The application B update to table X (BT1) is not presented because XLA is not set up to detect changes to table X.

- The application A updates to table Z (AT1 and AT2) are never presented because it did not commit and was rolled back (AT3).

About XLA and materialized views

You can use XLA to track changes to both tables and materialized views. A materialized view provides a single source from which you can track changes to selected rows and columns in multiple detail tables. Without a materialized view, the XLA application would have to monitor and filter the update records from all of the detail tables, including records reflecting updates to rows and columns of no interest to the application.

In general, there are no operational differences between the XLA mechanisms used to track changes to a table or a materialized view. However, for asynchronous materialized views, be aware that the order of XLA notifications for an asynchronous

materialized view is not necessarily the same as it would be for the associated detail tables, or the same as it would be for a synchronous materialized view. For example, if there are two inserts to a detail table, they may be done in the opposite order in the asynchronous materialized view. Furthermore, an update to a detail table of a materialized view may be reported by XLA as a delete followed by an insert. Also, multiple operations, such as multiple inserts or multiple deletes, may be combined into a single operation. Applications that depend on precise ordering should not use asynchronous materialized views.

For more information about materialized views, see the following:

- "CREATE MATERIALIZED VIEW" in *Oracle TimesTen In-Memory Database SQL Reference*

- "Understanding materialized views" in *Oracle TimesTen In-Memory Database Operations Guide*

About XLA bookmarks

Each XLA reader uses a bookmark to maintain its position in the log update stream. Each bookmark consists of two pointers that track update records in the transaction log by using *log record identifiers*:

- An Initial Read log record identifier points to the most recently acknowledged transaction log record. Initial Read log record identifiers are stored in the database, so they are persistent across database connections, shutdowns, and failures.

- A Current Read log record identifier points to the record currently being read from the transaction log.

The rest of this section covers the following:

- Creating or reusing a bookmark

- How bookmarks work

- Replicated bookmarks

- XLA bookmarks and transaction log holds

Creating or reusing a bookmark

As described in "Initializing XLA and obtaining an XLA handle" on page 5-11, when you call the `ttXlaPersistOpen` function to initialize an XLA handle, you have a *tag* parameter to identify either a new bookmark or one that exists in the system, and an *options* parameter to specify whether it is a new non-replicated bookmark, a new replicated bookmark, or an existing (reused) bookmark. At this time, the Initial Read log record identifier associated with the bookmark is read from the database and cached in the XLA handle (`ttXlaHandle_h`). It designates the start position of the reader in the transaction log.

See "ttLogHolds" in *Oracle TimesTen In-Memory Database Reference* for related information. That TimesTen built-in procedure returns information about transaction log holds.
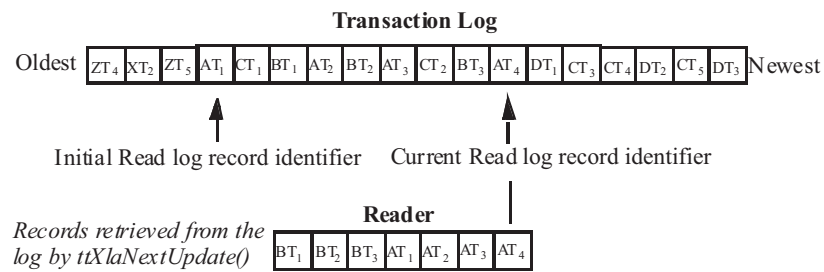

How bookmarks work

When an application first initializes XLA and obtains an XLA handle, its Current Read log record identifier and Initial Read log record identifier both point to the last record written to the database, as shown in Figure 5–2 that follows.

**Figure 5–2   Log record indicator positions upon initializing an XLA handle**

Transaction Log

Oldest | ---------------- | FT_1 | ZT_1 | QT_1 | FT_2 | QT_2 | FT_3 | ZT_2 | QT_3 | QT_4 | XT_1 | ZT_3 | ZT_4 | XT_2 | ZT_5 | AT_1 | Newest

Initial Read log record identifier
Current Read log record identifier
As described in "Retrieving update records from the transaction log" on page 5-13, use the `ttXlaNextUpdate` or `ttXlaNextUpdateWait` function to return a batch of records for committed transactions from the transaction log in the order in which they were committed. Each call to `ttXlaNextUpdate` resets the Current Read log record identifier of the bookmark to the last record read, as shown in Figure 5–3. The Current Read log record identifier marks the start position for the next call to `ttXlaNextUpdate`.

Figure 5–3   Records retrieved by ttXlaNextUpdate

Transaction Log

Oldest | ZT_4 | XT_2 | ZT_5 | AT_1 | CT_1 | BT_1 | AT_2 | BT_2 | AT_3 | CT_2 | BT_3 | AT_4 | DT_1 | CT_3 | CT_4 | DT_2 | CT_5 | DT_3 | Newest

Initial Read log record identifier   Current Read log record identifier

Records retrieved from the log by ttXlaNextUpdate()

Reader

BT_1 | BT_2 | BT_3 | AT_1 | AT_2 | AT_3 | AT_4

You can use the `ttXlaGetLSN` and `ttXlaSetLSN` functions to reread records, as described in "Changing the location of a bookmark" on page 5-39. However, calling the `ttXlaAcknowledge` function permanently resets the Initial Read log record identifier of the bookmark to its Current Read log record identifier, as shown in Figure 5–4. After you have called the `ttXlaAcknowledge` function to reset the Initial Read log record identifier, all previously read transaction records are flagged for purging by TimesTen. Once the Initial Read log record identifier is reset, you cannot use `ttXlaSetLSN` to go back and reread any of the previously read transactions.

Figure 5–4   ttXlaAcknowledge resets bookmark

Transaction Log

Records flagged for purging

Oldest | ---------------- | ▨▨▨▨▨▨▨▨▨▨▨▨ | AT_4 | DT_1 | CT_3 | CT_4 | DT_2 | CT_5 | DT_3 | Newest

Initial Read log record identifier
Current Read log record identifier

Reader

ttXlaAcknowledge()

BT_1 | BT_2 | BT_3 | AT_1 | AT_2 | AT_3 | AT_4

Note: A `ttXlaAcknowledge` call will reset the bookmark even if there are no relevant update records to acknowledge. This may be useful in managing transaction log space, but should be balanced against the expense of the operation. Be aware that XLA purges transaction logs a file at a time. Refer to "ttXlaAcknowledge" on page 9-6 for details on how the operation works.

The number of bookmarks created in a database is limited to 64. Each bookmark can be associated with only one active connection at a time. However, a bookmark over its lifetime may be associated with many connections. An application can open a connection, create a new bookmark, associate the bookmark with the connection, read a few records using the bookmark, disconnect from the database, reconnect to the database, create a new connection, associate this new connection with the bookmark, and continue reading transaction log records from where the old connection stopped.

Replicated bookmarks

If you are using an active standby pair replication scheme, you have the option of using *replicated bookmarks* according to the *options* settings in your `ttXlaPersistOpen` calls. For a replicated bookmark, operations on the bookmark are replicated to the standby database as appropriate. This results in more efficient recovery of your bookmark positions in the event of failover. Reading resumes from the stream of XLA records close to the point at which they left off before the switchover to the new active store. Without replicated bookmarks, reading must go through numerous duplicate records that were returned on the old active store.

You can only read and acknowledge a replicated bookmark in the active database. Each time you acknowledge a replicated bookmark, the acknowledge operation is asynchronously replicated to the standby database.

Be aware of the following usage notes:

- The position of the bookmark in the standby database will be very close to that of the bookmark in the active database; however, because the replication of acknowledge operations is asynchronous, you may see a small window of duplicate updates in the event of a failover, depending on how often acknowledge operations are performed.

- It is recommended that you close and reopen all bookmarks on a database after it changes from standby to active status, using the `ttXlaClose` and `ttXlaPersistOpen` functions. The state of a replicated bookmark on a standby database does change during normal XLA processing, as the replication agent automatically repositions bookmarks as appropriate on standby databases. If you attempt to use a bookmark that was open before the database changed to active status, you will receive an error indicating that the state of the bookmark was reset and that it has been repositioned. While it is permissible to continue reading from the repositioned bookmark in this scenario, you can avoid the error by closing and reopening bookmarks.

- If replicated bookmarks exist at the time you enable the active standby pair scheme, the bookmarks will automatically be added to the replication scheme.

- It is permissible to drop the active standby pair scheme while replicated bookmarks exist. The bookmarks will cease to be replicated at that point.

- You cannot delete replicated bookmarks as long as the replication agent is running.

XLA bookmarks and transaction log holds

You should be aware that when XLA is in use, there is a hold on TimesTen transaction log files until the XLA bookmark advances. The hold prevents transaction log files from being purged until XLA can confirm it no longer needs them. If a bookmark becomes stuck, which can occur if an XLA application terminates unexpectedly or disconnects without first deleting its bookmark or disabling change tracking, the log hold will persist and there may be an excessive accumulation of transaction log files. This accumulation may result in disk space being filled.

For information about monitoring and addressing this situation, see "Monitoring accumulation of transaction log files" in *Oracle TimesTen In-Memory Database Operations Guide*.

About XLA data types

Table 5–1 shows the data type mapping between internal SQL data types and XLA data types before release 7.0 and since release 7.0. For more information about TimesTen data types, see "Data Types" in *Oracle TimesTen In-Memory Database SQL Reference*.

Table 5–1   XLA data type mapping

Internal SQL data type	XLA data type before Release 7.0	XLA data type since Release 7.0
TT_CHAR	SQL_CHAR	TTXLA_CHAR_TT
TT_VARCHAR	SQL_VARCHAR	TTXLA_VARCHAR_TT
TT_NCHAR	SQL_WCHAR	TTXLA_NCHAR_TT
TT_NVARCHAR	SQL_WVARCHAR	TTXLA_NVARCHAR_TT
CHAR	-	TTXLA_CHAR
NCHAR	-	TTXLA_NCHAR
VARCHAR2	-	TTXLA_VARCHAR
NVARCHAR2	-	TTXLA_NVARCHAR
TT_TINYINT	SQL_TINYINT	TTXLA_TINYINT
TT_SMALLINT	SQL_SMALLINT	TTXLA_SMALLINT
TT_INTEGER	SQL_INTEGER	TTXLA_INTEGER
TT_BIGINT	SQL_BIGINT	TTXLA_BIGINT
BINARY_FLOAT	SQL_REAL	TTXLA_BINARY_FLOAT
BINARY_DOUBLE	SQL_DOUBLE	TTXLA_BINARY_DOUBLE
TT_DECIMAL	SQL_DECIMAL	TTXLA_DECIMAL_TT
NUMBER	-	TTXLA_NUMBER
NUMBER(*p*,*s*)	-	TTXLA_NUMBER
FLOAT	-	TTXLA_NUMBER
TT_TIME	SQL_TIME	TTXLA_TIME
TT_DATE	SQL_DATE	TTXLA_DATE_TT
TT_TIMESTAMP	SQL_TIMESTAMP	TTXLA_TIMESTAMP_TT
DATE	-	TTXLA_DATE
TIMESTAMP	-	TTXLA_TIMESTAMP
TT_BINARY	SQL_BINARY	TTXLA_BINARY
TT_VARBINARY	SQL_VARBINARY	TTXLA_VARBINARY
ROWID	-	TTXLA_ROWID
BLOB	-	TTXLA_BLOB
CLOB	-	TTXLA_CLOB
NCLOB	-	TTXLA_NCLOB

XLA offers functions to convert between internal SQL data types and external programmatic data types. For example, you can use `ttXlaNumberToCString` to convert `NUMBER` columns to character strings. TimesTen provides the following XLA data type conversion functions:

- `ttXlaDateToODBCCType`
- `ttXlaDecimalToCString`
- `ttXlaNumberToCString`
- `ttXlaNumberToDouble`
- `ttXlaNumberToBigInt`
- `ttXlaNumberToInt`
- `ttXlaNumberToSmallInt`
- `ttXlaNumberToTinyInt`
- `ttXlaNumberToUInt`
- `ttXlaOraDateToODBCTimeStamp`
- `ttXlaOraTimeStampToODBCTimeStamp`
- `ttXlaRowidToCString`
- `ttXlaTimeToODBCCType`
- `ttXlaTimeStampToODBCCType`

Access control impact on XLA

"Considering TimesTen features for access control" on page 2-33 provides a brief overview of how TimesTen access control affects operations in the database. Access control impacts XLA as follows:

- Any XLA functionality, such as the following, requires the system privilege `XLA`:
  - Connecting to TimesTen (which also requires the `CREATE SESSION` privilege) as an XLA reader, such as by the `ttXlaPersistOpen` C function
  - Executing any other XLA-related TimesTen C functions, documented in Chapter 9, "XLA Reference"
  - Executing any XLA-related TimesTen built-in procedures

    The procedures `ttXlaBookmarkCreate`, `ttXlaBookmarkDelete`, `ttXlaSubscribe`, and `ttXlaUnsubscribe` are documented in "Built-In Procedures" in *Oracle TimesTen In-Memory Database Reference*.

- A user with the `XLA` privilege has capabilities equivalent to the `SELECT ANY TABLE`, `SELECT ANY VIEW`, and `SELECT ANY SEQUENCE` system privileges, and can capture DDL statement records that occur in the database. Note that as a result, the user can obtain information about database objects that he or she has not otherwise been granted access to.

XLA limitations

Be aware of the following limitations when you use TimesTen XLA:

- XLA is available on all platforms supported by TimesTen. However, XLA does not support data transfer between different platforms or between 32-bit and 64-bit versions of the same platform.

- XLA support for LOBs is limited. See "Specifying which tables to monitor for updates" on page 5-11 for information.

- XLA does not support applications linked with a driver manager library or the client/server library.

- An XLA reader cannot subscribe to a table that uses in-memory columnar compression.

- For autorefresh cache groups, the change-tracking trigger on Oracle does not have column-level resolution. (To have that would be very expensive.) Therefore the autorefresh feature will update all the columns in the row, and XLA can only report that all the columns have changed, even if data did not actually change in all columns.

XLA demo

TimesTen provides the `xlaSimple` demo showing how to use many of the XLA functions described in this chapter. It is located in the `quickstart/sample_code/odbc/xla` directory:

See "About the TimesTen C demos" on page 1-5 for an overview of TimesTen demo programs for C developers. Refer to *install_dir*/`quickstart.html` for details. The README file in the `odbc` directory contains instructions for building and running `xlaSimple`, among others.

Most of this chapter, including the sample code shown in "Writing an XLA event-handler application" starting immediately below, is based on the `xlaSimple` demo. For this demo, a table MYDATA has been created in the APPUSER schema. While you are logged in as APPUSER, you will be making updates to the table. While you are logged in as XLAUSER, the `xlaSimple` demo reports on the updates.

To run the demo, execute `xlaSimple` at one command prompt. You will be prompted for the password of XLAUSER, which is specified when the sample database is created. Start `ttIsql` at a separate command prompt, connecting to the TimesTen sample database as APPUSER. Again, you will be prompted for a password that is specified when the sample database is created.

At the `ttIsql` command prompt you can enter DML statements to alter the table. Then you can view the XLA output in the `xlaSimple` window.

Writing an XLA event-handler application

This section describes the general procedures for writing an XLA application that detects and reports changes to selected tables in a database. With the possible exception of "Inspecting column data" on page 5-17, the procedures described in this section are applicable to most XLA applications.

The following procedures are described:

- Obtaining a database connection handle

- Initializing XLA and obtaining an XLA handle

- Specifying which tables to monitor for updates

- Retrieving update records from the transaction log

- Inspecting record headers and locating row addresses

- Inspecting column data

- [Handling XLA errors](#)
- [Dropping a table that has an XLA bookmark](#)
- [Deleting bookmarks](#)
- [Terminating an XLA application](#)

The example code in this section is based on the xlaSimple demo application.

XLA functions mentioned here are documented in Chapter 9, "XLA Reference".

> **Important:** In addition to files noted in "TimesTen include files" on page 2-7, an XLA application must include tt_xla.h.

> **Note:** To simplify the code examples, routine error checking code for each function call has been omitted. See "Handling XLA errors" on page 5-28 for information on error handling.

Obtaining a database connection handle

As with every ODBC application, an XLA application must initialize ODBC, obtain an environment handle (henv), and obtain a connection handle (hdbc) to communicate with the specific database.

Initialize the environment and connection handles:

```
SQLHENV henv = SQL_NULL_HENV;
SQLHDBC hdbc = SQL_NULL_HDBC;
```

Pass the address of henv to the SQLAllocEnv ODBC function to allocate an environment handle:

```
rc = SQLAllocEnv(&henv);
```

Pass the address of hdbc to the SQLAllocConnect ODBC function to allocate a connection handle for the database:

```
rc = SQLAllocConnect(henv, &hdbc);
```

Call the SQLDriverConnect ODBC function to connect to the database specified by the connection string (connStr), which in this example is passed from the command line:

```
static char connstr[CONN_STR_LEN];
...
rc = SQLDriverConnect(hdbc, NULL, (SQLCHAR*)connstr, SQL_NTS, NULL, 0,
                      NULL, SQL_DRIVER_COMPLETE);
```

> **Note:** After an ODBC connection handle is opened for use by an XLA application, the ODBC handle cannot be used for ODBC operations until the corresponding XLA handle is closed by calling ttXlaClose.

Call the SQLSetConnectOption ODBC function to turn autocommit off:

```
rc = SQLSetConnectOption(hdbc, SQL_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF);
```

Initializing XLA and obtaining an XLA handle

After initializing ODBC and obtaining an environment and connection handle as described in the preceding section, "Obtaining a database connection handle", you can initialize XLA and obtain an XLA handle to access the transaction log. Create only one XLA handle per ODBC connection. If your application uses multiple XLA reader threads (each connected to its own XLA bookmark), create a separate XLA handle and ODBC connection for each thread.

This section describes how to initialize XLA.

Before initializing XLA, initialize a bookmark. Then initialize an XLA handle as type `ttXlaHandle_h`:

```
unsigned char bookmarkName [32];
...
strcpy((char*)bookmarkName, "xlaSimple");
...
ttXlaHandle_h xla_handle = NULL;
```

Pass `bookmarkName` and the address of `xla_handle` to the `ttXlaPersistOpen` function to obtain an XLA handle:

```
rc = ttXlaPersistOpen(hdbc, bookmarkName, XLACREAT, &xla_handle);
```

The `XLACREAT` option is used to create a new non-replicated bookmark. Alternatively, use the `XLAREPL` option to create a replicated bookmark. In either case, the operation will fail if the bookmark already exists.

To use a bookmark that already exists, call `ttXlaPersistOpen` with the `XLAREUSE` option, as shown in the following example.

```
#include <tt_errCode.h>      /* TimesTen Native Error codes */
...
    if ( native_error == 907 ) { /* tt_ErrKeyExists */
      rc = ttXlaPersistOpen(hdbc, bookmarkName, XLAREUSE, &xla_handle);
    ...
    }
```

If `ttXlaPersistOpen` is given invalid parameters, or the application was unable to allocate memory for the handle, the return code will be `SQL_INVALID_HANDLE`. In this situation, `ttXlaError` cannot be used to detect this or any further errors.

If `ttXlaPersistOpen` fails but still creates a handle, the handle must be closed to prevent memory leaks.

Specifying which tables to monitor for updates

After initializing XLA and obtaining an XLA handle as described in the preceding section, "Initializing XLA and obtaining an XLA handle", you can specify which tables or materialized views you want to monitor for update events.

You can determine which tables a bookmark is subscribed to by querying the `SYS.XLASUBSCRIPTIONS` table. You can also use `SYS.XLASUBSCRIPTIONS` to determine which bookmarks have subscribed to a specific table.

The `ttXlaNextUpdate` and `ttXlaNextUpdateWait` functions retrieve XLA records associated with DDL events. DDL XLA records are available to any XLA bookmark. DDL events include `CREATAB`, `DROPTAB`, `CREAIND`, `DROPIND`, `CREATVIEW`, `DROPVIEW`, `CREATSEQ`, `DROPSEQ`, `CREATSYN`, `DROPSYN`, `ADDCOLS`, `DRPCOLS`, and `TRUNCATE` transactions. See "ttXlaUpdateDesc_t" on page 9-65 for information about these event types.

The `ttXlaTableStatus` function subscribes the current bookmark to updates to the specified table. Or it determines whether the current bookmark is already monitoring DML records associated with the table.

Call the `ttXlaTableByName` function to obtain both the system and user identifiers for a named table or materialized view. Then call the `ttXlaTableStatus` function to enable XLA to monitor changes to the table or materialized view.

> **Note:** LOB support in XLA is limited, as follows:
>
> - You can subscribe to tables containing LOB columns, but information about the LOB value itself is unavailable.
>
> - `ttXlaGetColumnInfo` returns information about LOB columns.
>
> - Columns containing LOBs are reported as empty (zero length) or null (if the value is actually `NULL`). In this way, you can tell the difference between a null column and a non-null column.

Example 5–2   Specifying a table to monitor for updates

This example tracks changes to the `MYDATA` table:

```
#define TABLE_OWNER "APPUSER"
#define TABLE_NAME "MYDATA"
...
SQLUBIGINT SYSTEM_TABLE_ID = 0;
...
SQLUBIGINT userID;

rc = ttXlaTableByName(xla_handle, TABLE_OWNER, TABLE_NAME,
                      &SYSTEM_TABLE_ID, &userID);
```

When you have the table identifiers, you can use the `ttXlaTableStatus` function to enable XLA update tracking to detect changes to the `MYDATA` table. Setting the `newstatus` parameter to a nonzero value results in XLA tracking changes made to the specified table:

```
SQLINTEGER oldstatus;
SQLINTEGER newstatus = 1;
...
rc = ttXlaTableStatus(xla_handle, SYSTEM_TABLE_ID, 0,
                      &oldstatus, &newstatus);
```

The `oldstatus` parameter is output to indicate the status of the table at the time of the call.

At any time, you can use `ttXlaTableStatus` to return the current XLA status of a table by leaving `newstatus` null and returning only `oldstatus`. For example:

```
rc = ttXlaTableStatus(xla_handle, SYSTEM_TABLE_ID, 0,
                      &oldstatus, NULL);
...
if (oldstatus != 0)
     printf("XLA is currently tracking changes to table %s.%s\n",
            TABLE_OWNER, TABLE_NAME);
else
     printf("XLA is not tracking changes to table %s.%s\n",
            TABLE_OWNER, TABLE_NAME);
```

Retrieving update records from the transaction log

Once you have specified which tables to monitor for updates, you can call the `ttXlaNextUpdate` or `ttXlaNextUpdateWait` function to return a batch of records from the transaction log. Only records for committed transactions are returned. They are returned in the order in which they were committed. You must periodically call the `ttXlaAcknowledge` function to acknowledge receipt of the transactions so that XLA can determine which records are no longer needed and can be purged from the transaction log. These functions impact the position of the application bookmark in the transaction log, as described in "How bookmarks work" on page 5-4. Also see "ttLogHolds" in *Oracle TimesTen In-Memory Database Reference* for related information. That TimesTen built-in procedure returns information about transaction log holds.

> **Note:** The `ttXlaAcknowledge` function is an expensive operation and should be used only as necessary.

Each update record in a transaction returned by `ttXlaNextUpdate` begins with an update header described by the `ttXlaUpdateDesc_t` structure. This update header contains a flag indicating if the record is the first in the transaction (`TT_UPDFIRST`) or the last commit record (`TT_UPDCOMMIT`). The update header also identifies the table affected by the update. Following the update header are zero to two rows of data that describe the update made to that table in the database.

Figure 5–5 that follows shows a call to `ttXlaNextUpdate` that returns a transaction consisting of four update records from the transaction log. Receipt of the returned transaction is acknowledged by calling `ttXlaAcknowledge`, which resets the bookmark.

> **Note:** This example is simplified for clarity. An actual XLA application would likely read records for multiple transactions before calling `ttXlaAcknowledge`.

Figure 5–5   Update records
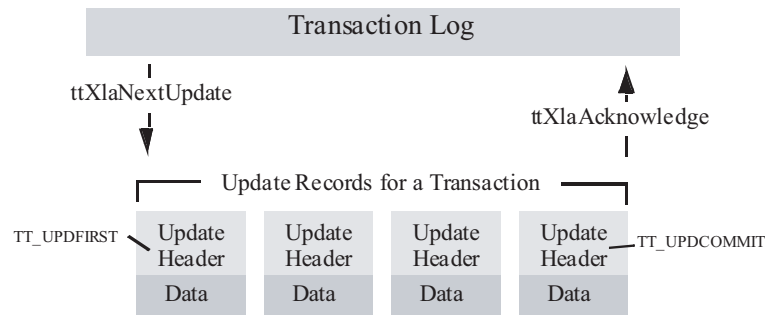

Example 5–3   Retrieving update records from the transaction log

The `xlaSimple` demo continues to monitor our table for updates until stopped by the user.

Before calling `ttXlaNextUpdateWait`, the example initializes a pointer to the buffer to hold the returned `ttXlaUpdateDesc_t` records (`arry`) and a variable to hold the actual number of returned records (`records`). Because the example calls `ttXlaNextUpdateWait`, it also specifies the number of seconds to wait (`FETCH_WAIT_SECS`) if no records are found in the transaction log buffer.

Next, call `ttXlaNextUpdateWait`, passing these values to obtain a batch of
`ttXlaUpdateDesc_t` records in `arry`. Then process each record in `arry` by passing it to
the `HandleChange()` function described in Example 5–4 on page 5-16. After all records
are processed, call `ttXlaAcknowledge` to reset the bookmark position.

```
#define FETCH_WAIT_SECS 5
...
SQLINTEGER records;
ttXlaUpdateDesc_t** arry;
int j;

while (!StopRequested()) {

    /* Get a batch of update records */
    rc = ttXlaNextUpdateWait(xla_handle, &arry, 100,
                             &records, FETCH_WAIT_SECS);
    if (rc != SQL_SUCCESS {
      /* See "Handling XLA errors" on page 5-28 */
    }

    /* Process the records */
    for(j=0; j < records; j++){
      ttXlaUpdateDesc_t* p;
      p = arry[j];
      HandleChange(p); /* Described in the next section */
    }

    /* After each batch, Acknowledge updates to reset bookmark.*/
    rc = ttXlaAcknowledge(xla_handle);
    if (rc != SQL_SUCCESS {
      /* See "Handling XLA errors" on page 5-28 */
    }
} /* end while !StopRequested() */
```

The actual number of records returned by `ttXlaNextUpdate` or `ttXlaNextUpdateWait`,
as indicated by the *nreturned* output parameter of those functions, may be less than
the value of the *maxrecords* parameter. Figure 5–6 shows an example where
maxrecords is 10, the transaction log contains transaction `AT` that is made up of seven
records, and transaction `BT` that is made up of three records. In this case, both
transactions are returned in the same batch and both *maxrecords* and *nreturned*
values are 10. However, the next three transactions in the log are `CT` with 11 records,
`DT` with two records, and `ET` with two records. Because the commit record for the `DT`
transaction appears before the `CT` commit record, the next call to `ttXlaNextUpdate`
returns the two records for the `DT` transaction and the value of *nreturned* is 2. In the
next call to `ttXlaNextUpdate`, XLA detects that the total records for the `CT` transaction
exceeds *maxrecords*, so it returns the records for this transaction in two batches. The
first batch contains the first 10 records for `CT` (*nreturned* = 10). The second batch
contains the last `CT` record and the two records for the `ET` transaction, assuming no
commit record for a transaction following `ET` is detected within the next seven records.

See "ttXlaNextUpdate" on page 9-22 and "ttXlaNextUpdateWait" on page 9-24 for
details of the parameters of these functions.

Figure 5–6   Records retrieved when maxrecords=10
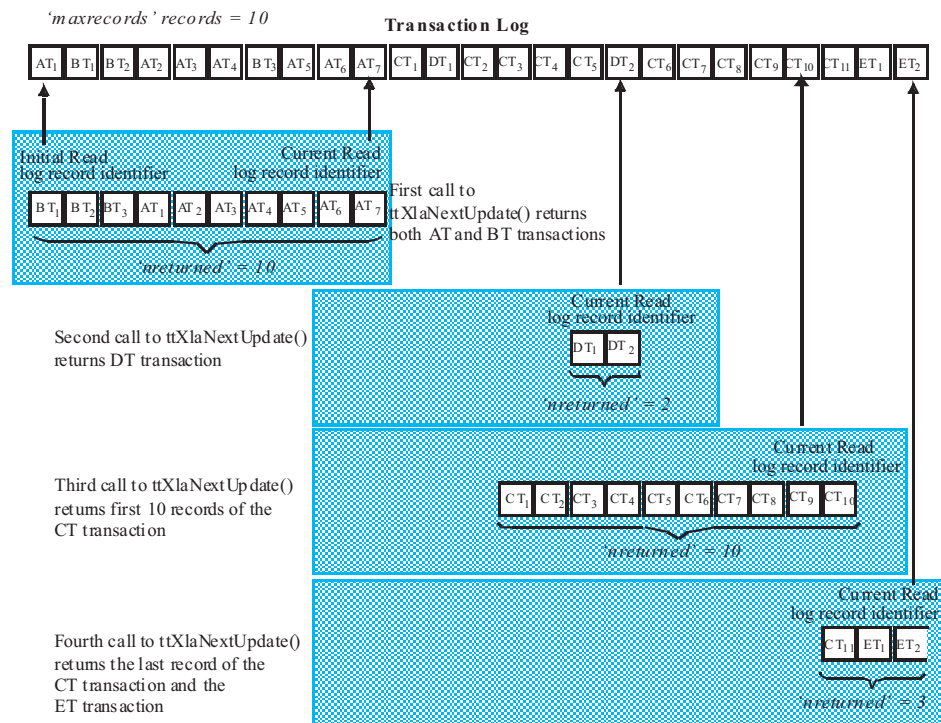

XLA reads records from either a memory buffer or transaction log files on disk, as described in "How XLA reads records from the transaction log" on page 5-2. To minimize latency, records from the memory buffer are returned as soon as they are available, while records not in the buffer are returned only if the buffer is empty. This design enables XLA applications to see changes as soon as the changes are made and with minimal latency. The trade-off is that there may be times when fewer changes are returned than the number requested by the `ttXlaNextUpdate` or `ttXlaNextUpdateWait` `maxrecords` parameter.

> **Note:**   For optimal throughput, XLA applications should make the "fetch" and "process record" procedures asynchronous. For example, you can create one thread to fetch and store the records and one or more other threads to process the stored records.

Inspecting record headers and locating row addresses

Now that there is an array of update records where the type of operation each record represents is known, the returned row data can be inspected.

Each record returned by the `ttXlaNextUpdate` or `ttXlaNextUpdateWait` function begins with an `ttXlaUpdateDesc_t` header that describes the following:

- The table on which the operation was performed

- Whether the record is the first or last (commit) record in the transaction

- The type of operation it represents

- The length of the returned row data, if any

- Which columns in the row were updated, if any

Figure 5–7 shows one of the update records in the transaction log.

Figure 5–7 Address of row data returned in an XLA update record
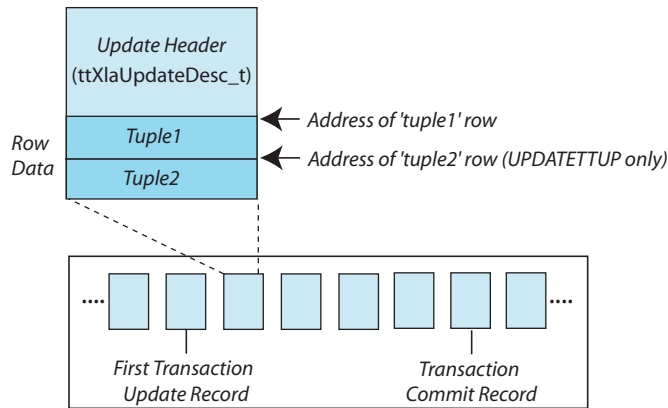

The `ttXlaUpdateDesc_t` header has a fixed length and, depending on the type of operation, is followed by zero to two rows (or tuples) from the database. You can locate the address of the first returned row by obtaining the address of the `ttXlaUpdateDesc_t` header and adding it to `sizeof(ttXlaUpdateDesc_t)`:

```
tup1 = (void*) ((char*) ttXlaUpdateDesc_t + sizeof(ttXlaUpdateDesc_t));
```

This is shown in Example 5–4 below.

The `ttXlaUpdateDesc_t ->type` field describes the type of SQL operation that generated the update. Transaction records of type `UPDATETTUP` describe `UPDATE` operations, so they return two rows to report the row data before and after the update. You can locate the address of the second returned row that holds the value after the update by adding the address of the first row in the record to its length:

```
if (ttXlaUpdateDesc_t->type == UPDATETUP) {
  tup2 = (void*) ((char*) tup1 + ttXlaUpdateDesc_t->tuple1);
}
```

This is also shown in Example 5–4.

Example 5–4   Inspecting record headers for SQL operation type

This example passes each record returned by the `ttXlaNextUpdateWait` function to a `HandleChange()` function, which determines whether the record is related to an `INSERT`, `UPDATE`, or `CREATE VIEW` operation. To keep this example simple, all other operations are ignored.

The `HandleChange()` function handles each type of SQL operation differently before calling the `PrintColValues()` function described in Example 5–13 on page 5-25.

```
void HandleChange(ttXlaUpdateDesc_t* xlaP)
{
  void*  tup1;
  void*  tup2;

  /* First confirm that the XLA update is for the table we care about. */
  if (xlaP->sysTableID != SYSTEM_TABLE_ID)
    return ;

  /* OK, it's for the table we're monitoring. */

  /* The last record in the ttXlaUpdateDesc_t record is the "tuple2"
   * field.  Immediately following this field is the first XLA record "row". */
```

```
tup1 = (void*) ((char*) xlaP + sizeof(ttXlaUpdateDesc_t));

switch(xlaP->type) {

case INSERTTUP:
  printf("Inserted new row:\n");
  PrintColValues(tup1);
  break;

case UPDATETUP:

  /* If this is an update ttXlaUpdateDesc_t, then following that is
   * the second XLA record "row".
   */

  tup2 = (void*) ((char*) tup1 + xlaP->tuple1);
  printf("Updated row:\n");
  PrintColValues(tup1);
  printf("To:\n");
  PrintColValues(tup2);
  break;

case DELETETUP:
  printf("Deleted row:\n");
  PrintColValues(tup1);
  break;

default:
  /* Ignore any XLA records that are not for inserts/update/delete SQL ops. */
  break;

} /* switch (xlaP->type) */
}
```

Inspecting column data

As described in "Inspecting record headers and locating row addresses" on page 5-15, zero to two rows of data may be returned in an update record after the ttXlaUpdateDesc_t structure. For each row, the first portion of the data is the fixed-length data, which is followed by any variable-length data, as shown in Figure 5–8.

Figure 5–8   Column offsets in a row returned in an XLA update record
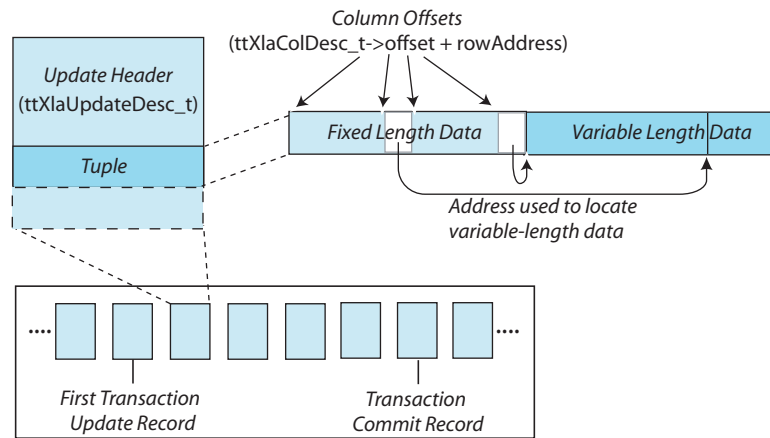

The procedures for inspecting column data are described in the following sections:

- Obtaining column descriptions

- Reading fixed-length column data

- Reading NOT INLINE variable-length column data

- Null-terminating returned strings

- Converting complex data types

- Detecting null values

- Putting it all together: a PrintColValues() function

Obtaining column descriptions

To read the column values from the returned row, you must first know the offset of each column in that row. The column offsets and other column metadata can be obtained for a particular table by calling the `ttXlaGetColumnInfo` function, which returns a separate `ttXlaColDesc_t` structure for each column in the table. You should call the `ttXlaGetColumnInfo` function as part of your initialization procedure. This call was omitted from the discussion in "Initializing XLA and obtaining an XLA handle" on page 5-11 for simplicity.

When calling `ttXlaGetColumnInfo`, specify a *colinfo* parameter to create a pointer to a buffer to hold the list of returned `ttXlaColDesc_t` structures. Use the *maxcols* parameter to define the size of the buffer.

Example 5–5   Using column descriptions

The sample code from the `xlaSimple` demo below guesses the maximum number of returned columns (`MAX_XLA_COLUMNS`), which sets the size of the buffer `xla_column_defs` to hold the returned `ttXlaColDesc_t` structures. An alternative and more precise way to set the *maxcols* parameter would be to call the `ttXlaGetTableInfo` function and use the value returned in `ttXlaColDesc_t ->columns`.

```
#define MAX_XLA_COLUMNS 128
...
SQLINTEGER ncols;
...
ttXlaColDesc_t xla_column_defs[MAX_XLA_COLUMNS];
...
```

```
rc = ttXlaGetColumnInfo(xla_handle, SYSTEM_TABLE_ID, userID,
            xla_column_defs, MAX_XLA_COLUMNS, &ncols);
  if (rc != SQL_SUCCESS {
    /* See "Handling XLA errors" on page 5-28 */
}
```

As shown in Figure 5–9, the `ttXlaGetColumnInfo` function produces the following output:

- A list, `xla_column_defs`, of `ttXlaColDesc_t` structures into the buffer pointed to by the `ttXlaGetColumnInfo` *colinfo* parameter.

- An *nreturned* value, `ncols`, that holds the actual number of columns returned in the `xla_column_defs` buffer.

Figure 5–9   ttXlaColDesc_t structures returned by ttXlaGetColumnInfo
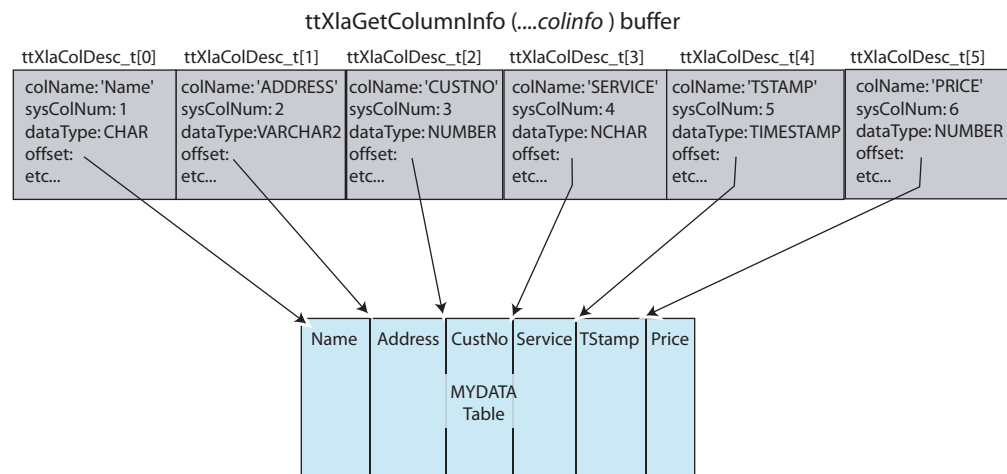

Each `ttXlaColDesc_t` structure returned by `ttXlaGetColumnInfo` has an offset value that describes the offset location of that column. How you use this offset value to read the column data depends on whether the column contains fixed-length data (such as `CHAR`, `NCHAR`, `INTEGER`, `BINARY`, `DOUBLE`, `FLOAT`, `DATE`, `TIME`, `TIMESTAMP`, and so on) or variable-length data (such as `VARCHAR`, `NVARCHAR`, or `VARBINARY`).

Reading fixed-length column data

For fixed-length column data, the address of a column is the offset value in the `ttXlaColDesc_t` structure, plus the address of the row.

Figure 5–10   Locating fixed-length data in a row
Example 5–6   Reading fixed-length column data

See Example 5–13 on page 5-25 for a complete working example of computations such as those shown here.

The first column in the MYDATA table is of type CHAR. If you use the address of the tup1 row obtained earlier in the HandleChange() function (Example 5–4 on page 5-16) and the offset from the first ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function (Example 5–5 on page 5-18), you can obtain the value of the first column with computations such as the following:

```
char*   Column1;

Column1 = ((unsigned char*) tup1 + xla_column_defs[0].offset);
```

The third column in the MYDATA table is of type INTEGER, so you can use the offset from the third ttXlaColDesc_t structure to locate the value and recast it as an integer using computations such as the following. The data is guaranteed to be aligned properly.

```
int Column3;

Column3 = *((int*) ((unsigned char*) tup +
          xla_column_defs[2].offset));
```

The fourth column in the MYDATA table is of type NCHAR, so you can use the offset from the fourth ttXlaColDesc_t structure to locate the value and recast it as a SQLWCHAR type, with computations such as the following:

```
SQLWCHAR*   Column4;

Column4 = (SQLWCHAR*) ((unsigned char*) tup +
                    xla_column_defs[3].offset);
```

Unlike the column values obtained in the above examples, Column4 points to an array of two-byte Unicode characters. You must iterate through each element in this array to obtain the string, as shown for the SQL_WCHAR case in Example 5–13 on page 5-25.

Other fixed-length data types can be cast to their corresponding C types. Complex fixed-length data types, such as DATE, TIME, and DECIMAL values, are stored in an internal TimesTen format, but can be converted by applications to their corresponding ODBC C value using the XLA conversion functions, as described in "Converting complex data types" on page 5-23.

> **Note:** Strings returned by XLA are not null-terminated. See "Null-terminating returned strings" on page 5-22.

Reading NOT INLINE variable-length column data

For NOT INLINE variable-length data (VARCHAR, NVARCHAR, and VARBINARY), the data located at ttXlaColDesc_t ->*offset* is a four-byte offset value that points to the location of the data in the variable-length portion of the returned row. By adding the offset address to the offset value, you can obtain the address of the column data in the variable-length portion of the row. The first *n* bytes (where *n* is 4 on 32-bit platforms or 8 on 64-bit platforms) at this location is the length of the data, followed by the actual data. For variable-length data, the ttXlaColDesc_t ->*size* value is the maximum allowable column size. Figure 5–11 shows how to locate NOT INLINE variable-length data in a row.

Figure 5–11   Locating NOT INLINE variable-length data in a row
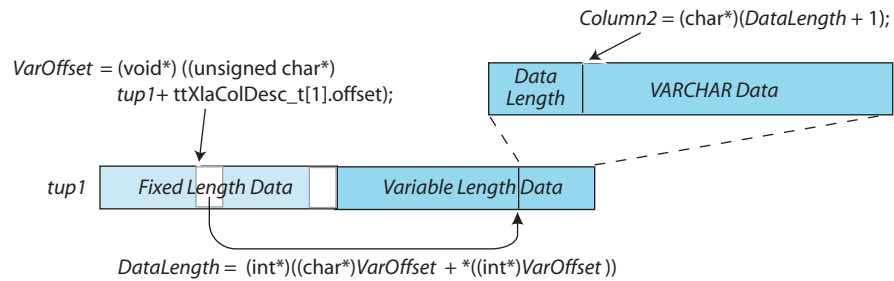

Example 5–7   Reading NOT INLINE variable-length column data

See Example 5–13, "Complete PrintColValues() function" for a complete working example of computations such as those shown here.

Continuing with our example, the second column in the returned row (tup1) is of type VARCHAR. To locate the variable-length data in the row, first locate the value at the column's ttXlaColDesc_t ->*offset* in the fixed-length portion of the row, as shown in Figure 5–11 above. The value at this address is the four-byte offset of the data in the variable-length portion of the row (VarOffset). Next, obtain a pointer to the beginning of the variable-length column data (DataLength) by adding the VarOffset offset value to the address of VarOffset. Assuming the operation is performed on a 32-bit platform, the first four bytes at the DataLength location is the length of the data. The next byte after DataLength is the beginning of the actual data (Column2).

The sample code here assumes the operation is performed on a 32-bit platform, so DataLength is initialized as a 32-bit type. On a 64-bit platform, DataLength must be initialized as a 64-bit type and the Column2 data would appear 64 bits + 1 after the offset address, DataLength.

```
void*  VarOffset; /* offset of data */
long*  DataLength; /* length of data */
char*  Column2; /* pointer to data */

VarOffset = (void*) ((unsigned char*) tup1 +
          xla_column_defs[1].offset);
    /*
     * If column is out-of-line, pColVal points to an offset
     * else column is inline so pColVal points directly to the string length.
     */

    if (xla_column_defs[1].flags & TT_COLOUTOFLINE)
    DataLength = (long*)((char*)VarOffset + *((int*)VarOffset));
    else
    DataLength = (long*)VarOffset;
    Column2 = (char*)(DataLength+1);
```

VARBINARY types are handled in a manner similar to VARCHAR types. If Column2 were an NVARCHAR type, you could initialize it as a SQLWCHAR, get the value as shown in the above VARCHAR case, then iterate through the Column2 array, as shown for the NCHAR value, CharBuf, in Example 5–13 on page 5-25.

> **Note:**   In the preceding example, DataLength is type long, which is described as being a 64-bit (8-byte) type on 64-bit systems and a 32-bit (4-byte) type on 32-bit systems. This is true on most UNIX systems; however, on Windows 64-bit systems long is a 4-byte type.

Null-terminating returned strings

Strings returned from record row data are not terminated with a null character. You can null-terminate a string by copying it into a buffer and adding a null character, '\0', after the last character in the string.

The procedures for null-terminating fixed-length and variable-length strings are slightly different. The procedure for null-terminating fixed-length strings is described in Example 5–8. Example 5–9 that follows describes the procedure for null-terminating variable-length strings of a known size. Example 5–10 then describes the procedure for strings of an unknown size.

Example 5–8   Null-terminating fixed-length strings

See Example 5–13 on page 5-25 for a complete working example of computations such as those shown here.

To null-terminate the fixed-length CHAR(10) Column1 string returned in Example 5–6 on page 5-19, establish a buffer large enough to hold the string plus null character. Next, obtain the size of the string from ttXlaColDesc_t ->*size*, copy the string into the buffer, and null-terminate the end of the string, using computations such as the following. You can now use the contents of the buffer. In this example, the string is printed:

```
char buffer[10+1];
int size;

size = xla_column_defs[0].size;
memcpy(buffer, Column1, size);
buffer[size] = '\0';

printf(" Row %s is %s\n", ((unsigned char*) xla_column_defs[0].colName), buffer);
```

Null-terminating a variable-length string is similar to the procedure for fixed-length strings, only the size of the string is the value located at the beginning of the variable-length data offset, as described in "Reading NOT INLINE variable-length column data" on page 5-20.

Example 5–9   Null-terminating variable-length strings of known size

(See Example 5–13 on page 5-25 for a complete working example of computations such as those shown here.)

If the Column2 string obtained in Example 5–7 on page 5-21 is a VARCHAR(32), establish a buffer large enough to hold the string plus null character. Use the value located at the DataLength offset to determine the size of the string, using computations such as the following:

```
char buffer[32+1];

memcpy(buffer, Column2, *DataLength);
buffer[*DataLength] = '\0';

printf(" Row %s is %s\n", ((unsigned char*) xla_column_defs[1].colName), buffer);
```

If you are writing general purpose code to read all data types, you cannot make any assumptions about the size of a returned string. For strings of an unknown size, statically allocate a buffer large enough to hold the majority of returned strings. If a returned string is larger than the buffer, dynamically allocate the correct size buffer, as shown in Example 5–10.

Example 5–10 Null-terminating variable-length strings of unknown size

If the `Column2` string obtained in Example 5–7 on page 5-21 is of an unknown size, you might statically allocate a buffer large enough to hold a string of up to 10000 characters. Then check that the `DataLength` value obtained at the beginning of the variable-length data offset is less than the size of the buffer. If the string is larger than the buffer, use `malloc()` to dynamically allocate the buffer to the correct size.

```
#define STACKBUFSIZE 10000
char VarStackBuf[STACKBUFSIZE];
char* buffer;

buffer = (*DataLength+1 <= STACKBUFSIZE) ? VarStackBuf :
           malloc(*DataLength+1);

memcpy(buffer,Column2,*DataLength);
buffer[*DataLength] = '\0';

printf(" Row %s is %s\n", ((unsigned char*) xla_column_defs[1].colName), buffer);
if (buffer != VarStackBuf) /* buffer was allocated */
        free(buffer);
```

Converting complex data types

Values for complex data types such as `TT_DATE`, `TT_TIME`, and `TT_DECIMAL` are stored in an internal TimesTen format that can be converted into corresponding ODBC C types using the XLA type conversion functions. Table 5–2 contains descriptions of these conversion functions.

Table 5–2 XLA data type conversion functions

Function	Converts
ttXlaDateToODBCCType	Internal TT_DATE value to an ODBC C value
ttXlaTimeToODBCCType	Internal TT_TIME value to an ODBC C value
ttXlaTimeStampToODBCCType	Internal TT_TIMESTAMP value to an ODBC C value
ttXlaDecimalToCString	Internal TT_DECIMAL value to a string value
ttXlaDateToODBCCType	Internal TTXLA_DATE_TT value to an ODBC C value
ttXlaDecimalToCString	Internal TTXLA_DECIMAL_TT value to a character string
ttXlaNumberToBigInt	Internal TTXLA_NUMBER value to a TT_BIGINT value
ttXlaNumberToCString	Internal TTXLA_NUMBER value to a character string
ttXlaNumberToDouble	Internal TTXLA_NUMBER value to a long floating point number value
ttXlaNumberToInt	Internal TTXLA_NUMBER value to an integer
ttXlaNumberToSmallInt	Internal TTXLA_NUMBER value to a TT_SMALLINT value
ttXlaNumberToTinyInt	Internal TTXLA_NUMBER value to a TT_TINYINT value
ttXlaNumberToUInt	Internal TTXLA_NUMBER value to an unsigned integer

Table 5–2   (Cont.) XLA data type conversion functions

Function	Converts
ttXlaOraDateToODBCTimeStamp	Internal TTXLA_DATE value to an ODBC timestamp
ttXlaOraTimeStampToODBCTimeStamp	Internal TTXLA_TIMESTAMP value to an ODBC timestamp
ttXlaTimeToODBCCType	Internal TTXLA_TIME value to an ODBC C value
ttXlaTimeStampToODBCCType	Internal TTXLA_TIMESTAMP_TT value to an ODBC C value

These conversion functions can be used on row data in the ttXlaUpdateDesc_t types: UPDATETUP, INSERTTUP and DELETETUP.

Example 5–11   Converting complex data types

(See Example 5–13 on page 5-25 for a complete working example of computations such as those shown here.)

If you use the address of the tup1 row obtained earlier in the HandleChange() function (Example 5–4 on page 5-16) and the offset from the fifth ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function (Example 5–5 on page 5-18), you can locate a column value of type TIMESTAMP. Use the ttXlaTimeStampToODBCCType function to convert the column data from TimesTen format and store the converted time value in an ODBC TIMESTAMP_STRUCT. You could use code such as the following to print the values:

```
void*  Column5;
TIMESTAMP_STRUCT timestamp;

Column5 = (void*) ((unsigned char*) tup1 +
                  xla_column_defs[4].offset);

rc = ttXlaTimeStampToODBCCType(Column5, &timestamp);
  if (rc != SQL_SUCCESS) {
    /* See "Handling XLA errors" on page 5-28 */
  }
printf(" %s: %04d-%02d-%02d %02d:%02d:%02d.%06d\n",
      ((unsigned char*) xla_column_defs[i].colName),
        timestamp.year,timestamp.month, timestamp.day,
        timestamp.hour,timestamp.minute,timestamp.second,
        timestamp.fraction);
```

If you use the address of the tup1 row obtained earlier in the HandleChange() function (Example 5–4) and the offset from the sixth ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function (Example 5–5), you can locate a column value of type DECIMAL. Use the ttXlaDecimalToCString function to convert the column data from TimesTen decimal format to a string. You could use code such as the following to print the values.

```
char decimalData[50];

Column6 = (float*) ((unsigned char*) tup +
          xla_column_defs[5].offset);
precision = (short) (xla_column_defs[5].precision);
scale = (short) (xla_column_defs[5].scale);
```

```
rc = ttXlaDecimalToCString(Column6, (char*)&decimalData,
                              precision, scale);
  if (rc != SQL_SUCCESS) {
    /* See "Handling XLA errors" on page 5-28 */
  }

printf(" %s: %s\n", ((unsigned char*) xla_column_defs[5].colName), decimalData);
```

Detecting null values

For nullable table columns, `ttXlaColDesc_t ->`*`nullOffset`* points to the column's null byte in the record. This field is 0 (zero) if the column is not nullable, or greater than 0 if the column can be null.

For nullable columns (`ttXlaColDesc_t ->`*`nullOffset`* > 0), to determine if the column is null, add the null offset to the address of `ttXlaUpdate_t*` and check the (`unsigned char`) byte there to see if it is 1 (`NULL`) or 0 (`NOT NULL`).

Example 5–12   Detecting null values

Check whether `Column6` is null as follows:

```
if (xla_column_defs[5].nullOffset != 0) {
  if (*((unsigned char*) tup +
     xla_column_defs[5].nullOffset) == 1) {
        printf("Column6 is NULL\n");
  }
}
```

Putting it all together: a PrintColValues() function

Example 5–13 shows a function that checks the `ttXlaColDesc_t ->`*`dataType`* of each column to locate columns with a data type of `CHAR`, `NCHAR`, `INTEGER`, `TIMESTAMP`, `DECIMAL`, and `VARCHAR`, then prints the values. This is just one possible approach. Another option, for example, would be to check the `ttXlaColDesc_t ->`*`ColName`* values to locate specific columns by name.

The `PrintColValues()` function handles `CHAR` and `VARCHAR` strings up to 50 bytes in length. `NCHAR` characters must belong to the ASCII character set.

Example 5–13   Complete PrintColValues() function

The function in this example first checks `ttXlaColDesc_t ->`*`nullOffset`* to see if the column is null. Next it checks the `ttXlaColDesc_t ->`*`dataType`* field to determine the data type for the column. For simple fixed-length data (`CHAR`, `NCHAR`, and `INTEGER`), it casts the value located at `ttXlaColDesc_t ->`*`offset`* to the appropriate C type. The complex data types, `TIMESTAMP` and `DECIMAL`, are converted from their TimesTen formats to ODBC C values using the `ttXlaTimeStampToODBCCType` and `ttXlaDecimalToCString` functions.

For variable-length data (`VARCHAR`), the function locates the data in the variable-length portion of the row, as described in "Handling XLA errors" on page 5-28.

```
void PrintColValues(void* tup)
{

  SQLRETURN rc ;
  SQLINTEGER native_error;

  void* pColVal;
```

```
char buffer[50+1]; /* No strings over 50 bytes */
int i;

for (i = 0; i < ncols; i++)
{

  if (xla_column_defs[i].nullOffset != 0) {  /* See if column is NULL */
    /* this means col could be NULL */
    if (*((unsigned char*) tup + xla_column_defs[i].nullOffset) == 1) {
      /* this means that value is SQL NULL */
      printf("  %s: NULL\n",
              ((unsigned char*) xla_column_defs[i].colName));
      continue; /* Skip rest and re-loop */
    }
  }

              if (rc != SQL_SUCCESS) {
                handleXLAerror (rc, xla_handle, err_buf, &native_error);
                fprintf(stderr, "ttXlaDecimalToCString() returns an error <%d>: %s",
                        rc, err_buf);
                TerminateGracefully(1);
              }

              printf("  %s: %s\n", ((unsigned char*) xla_column_defs[i].colName),
                     decimalData);
            }
            else if (xla_column_defs[i].dataType == TTXLA_NUMBER) {
              char numbuf[32];
              pColVal = (void*) ((unsigned char*) tup + xla_column_defs[i].offset);

              rc=ttXlaNumberToCString(xla_handle, pColVal, numbuf, sizeof(numbuf));
              if (rc != SQL_SUCCESS) {
                handleXLAerror (rc, xla_handle, err_buf, &native_error);
                fprintf(stderr, "ttXlaNumberToDouble() returns an error <%d>: %s",
                        rc, err_buf);
                TerminateGracefully(1);
              }
              printf("  %s: %s\n", ((unsigned char*) xla_column_defs[i].colName), numbuf);
            }

      } /* End FOR loop */
    }
```

Notes:

- In the preceding example, var_len is type long, assumed to be a 64-bit (8-byte) type on 64-bit systems and a 32-bit (4-byte) type on 32-bit systems. This is true on most UNIX systems; however, on Windows 64-bit systems long is a 4-byte type.

- See "Terminating an XLA application" on page 5-32 for a sample TerminateGracefully() method.

Handling XLA errors

Each time you call an ODBC or XLA function, you must check the return code for any errors. If the error is fatal, terminate the program as described in "Terminating an XLA application" on page 5-32.

An error can be checked using either its error code (error number) or tt_Err string. For the complete list of TimesTen error codes and error strings, see the *install_dir*/include/tt_errCode.h file. For a description of each message, see "List of errors and warnings" in *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps*.

If the return code from an XLA function is not SQL_SUCCESS, use the ttXlaError function to retrieve XLA-specific errors on the XLA handle.

Also see "Checking for errors" on page 2-35.

Example 5–14   Checking the return code and calling the error-handling function

This example, after calling the XLA function ttXlaTableByName, checks to see if the return code is SQL_SUCCESS. If not, it calls an XLA error-handling function followed by a function to terminate the application. See "Terminating an XLA application" on page 5-32.

```
rc = ttXlaTableByName(xla_handle, TABLE_OWNER, TABLE_NAME,
                      &SYSTEM_TABLE_ID, &userID);
if (rc != SQL_SUCCESS) {
  handleXLAerror (rc, xla_handle, err_buf, &native_error);
  fprintf(stderr,
    "ttXlaTableByName() returns an error <%d>: %s", rc, err_buf);
  TerminateGracefully(1);
}
```

Your XLA error-handling function should repeatedly call ttXlaError until all XLA errors are read from the error stack, proceeding until the return code from ttXlaError is SQL_NO_DATA_FOUND. If you must reread the errors, you can call the ttXlaErrorRestart function to reset the error stack pointer to the first error.

The error stack is cleared after a call to any XLA function other than ttXlaError or ttXlaErrorRestart.

> **Note:**   In cases where ttXlaPersistOpen cannot create an XLA handle, it returns the error code SQL_INVALID_HANDLE. Because no XLA handle has been created, ttXlaError cannot be used to detect this error. SQL_INVALID_HANDLE is returned only in cases where no memory can be allocated or the parameters provided are invalid.

Depending on your application, you may be required to act on specific XLA errors, including those shown in Table 5–3.

Table 5–3   XLA errors and codes

Error	Code
tt_ErrDbAllocFailed	802 (transient)
tt_ErrCondLockConflict	6001 (transient)
tt_ErrDeadlockVictim	6002 (transient)
tt_ErrTimeoutVictim	6003 (transient)
tt_ErrPermSpaceExhausted	6220 (transient)
tt_ErrTempSpaceExhausted	6221 (transient)
tt_ErrBadXlaRecord	8024
tt_ErrXlaBookmarkUsed	8029
tt_ErrXlaLsnBad	8031
tt_ErrXlaNoSQL	8034
tt_ErrXlaNoLogging	8035

Table 5–3 (Cont.) XLA errors and codes

Error	Code
tt_ErrXlaParameter	8036
tt_ErrXlaTableDiff	8037
tt_ErrXlaTableSystem	8038
tt_ErrXlaTupleMismatch	8046
tt_ErrXlaDedicatedConnection	8047

Example 5–15 Calling the handleXLAerror() function

This example shows handleXLAerror(), the error function for the xlaSimple demo program.

```
void handleXLAerror(SQLRETURN rc, ttXlaHandle_h xlaHandle,
                    SQLCHAR* err_msg, SQLINTEGER* native_error)
{
  SQLINTEGER retLen;
  SQLINTEGER code;

  char* err_msg_ptr;

  /* initialize return codes */
  rc = SQL_ERROR;
  *native_error = -1;
  err_msg[0] = '\0';

  err_msg_ptr = (char*)err_msg;

  while (1)
  {
    int rc = ttXlaError(xlaHandle, &code, err_msg_ptr,
                        ERR_BUF_LEN - (err_msg_ptr - (char*)err_msg), &retLen);
    if (rc == SQL_NO_DATA_FOUND)
    {
      break;
    }
    if (rc != SQL_SUCCESS && rc != SQL_SUCCESS_WITH_INFO) {
      sprintf(err_msg_ptr,
              "*** Error fetching error message via ttXlaError(); rc=<%d>.",rc) ;
      break;
    }
    rc = SQL_ERROR;
    *native_error = code ;
    /* append any other error messages */
    err_msg_ptr += retLen;
  }
}
```

Dropping a table that has an XLA bookmark

Before you can drop a table that is subscribed to by an XLA bookmark, you must unsubscribe the table from the bookmark. There are several ways to unsubscribe a table from a bookmark, depending on whether the application is connected to the bookmark.

If XLA applications are connected and using bookmarks that are tracking the table to be dropped, then perform the following tasks.

1. Each XLA application must call the `ttXlaTableStatus` function and set the *newstatus* parameter to 0. This unsubscribes the table from the XLA bookmark in use by the application.

2. Drop the table.

If XLA applications are not connected and using bookmarks associated with the table to be dropped, then perform the following tasks:

1. Query the `SYS.XLASUBSCRIPTIONS` system table to see which bookmarks have subscribed to the table you want to drop.

2. Use the `ttXlaUnsubscribe` built-in procedure to unsubscribe the table from each XLA bookmark with a subscription to the table.

3. Drop the table.

Deleting bookmarks also unsubscribes the table from the XLA bookmarks. See the next section, "Deleting bookmarks".

Deleting bookmarks

You may want to delete bookmarks when you terminate an application or drop a table. Use the `ttXlaDeleteBookmark` function to delete XLA bookmarks if the application is connected and using the bookmarks.

As described in "About XLA bookmarks" on page 5-4, a bookmark may be reused by a new connection after its previous connection has closed. The new connection can resume reading from the transaction log from where the previous connection stopped. Note the following:

■ If you delete the bookmark, subsequent checkpoint operations such as the `ttCkpt` or `ttCkptBlocking` built-in procedure will free the disk space associated with any unread update records in the transaction log.

■ If you do not delete the bookmark, when an XLA application connects and reuses the bookmark, all unread update records that have accumulated since the program terminated are read by the application. This is because the update records are persistent in the TimesTen transaction log. However, the danger is that these unread records can build up in the transaction log files and consume a lot of disk space.

> **Notes:**
>
> - You cannot delete replicated bookmarks while the replication agent is running.
>
> - When you reuse a bookmark, you start with the Initial Read log record identifier in the transaction log file. To ensure that a connection that reuses a bookmark begins reading where the prior connection left off, the prior connection should call `ttXlaAcknowledge` to reset the bookmark position to the currently accessed record before disconnecting.
>
> - See "ttLogHolds" in *Oracle TimesTen In-Memory Database Reference* for related information. That TimesTen built-in procedure returns information about transaction log holds.
>
> - Be aware that `ttCkpt` and `ttCkptBlocking` require `ADMIN` privilege. TimesTen built-in procedures and any required privileges are documented in "Built-In Procedures" in *Oracle TimesTen In-Memory Database Reference*.

Example 5–16 Deleting bookmarks

The `InitHandler()` function in the `xlaSimple` demo deletes the XLA bookmark upon exit, as shown in the following example.

```
if (deleteBookmark) {
    ttXlaDeleteBookmark(xla_handle);
    if (rc != SQL_SUCCESS) {
    /* See "Handling XLA errors" on page 5-28 */
    }
    xla_handle = NULL; /* Deleting the bookmark has the */
                       /* effect of disconnecting from XLA. */
}
/* Close the XLA connection as described in the next section,
"Terminating an XLA application". */
```

If the application is not connected and using the XLA bookmark, you can delete the bookmark either of the following ways:

- Close the bookmark and call the `ttXlaBookmarkDelete` built-in procedure.

- Close the bookmark and use the `ttIsql` command `xladeletebookmark`.

Terminating an XLA application

When your XLA application has finished reading from the transaction log, gracefully exit by rolling back uncommitted transactions and freeing all handles. There are two approaches to this:

- Unsubscribe from all tables and materialized views, delete the XLA bookmark, and disconnect from the database.

Or:

- Disconnect from the database but keep the XLA bookmark in place. When you reconnect at a later time, you can resume reading records from the bookmark.

For the first approach, complete the following steps.

1. Call `ttXlaTableStatus` to unsubscribe from each table and materialized view, setting the *newstatus* parameter to 0.

2. Call `ttXlaDeleteBookmark` to delete the bookmark. See "Deleting bookmarks" on page 5-31.

3. Call `ttXlaClose` to disconnect the XLA handle.

4. Call the ODBC function `SQLTransact` with the `SQL_ROLLBACK` setting to roll back any uncommitted transaction.

5. Call the ODBC function `SQLDisconnect` to disconnect from the TimesTen database.

6. Call the ODBC function `SQLFreeConnect` to free memory allocated for the ODBC connection handle.

7. Call the ODBC function `SQLFreeEnv` to free the ODBC environment handle.

For the second approach, maintaining the bookmark, skip the first two steps but complete the remaining steps.

Be aware that resources should be freed in reverse order of allocation. For example, the ODBC environment handle is allocated before the ODBC connection handle, so for cleanup free the connection handle before the environment handle.

Example 5–17   Terminating an XLA application

This example shows `TerminateGracefully()`, the termination function in the `xlaSimple` Quick Start demo.

```
void TerminateGracefully(int status)
{

  SQLRETURN     rc;
  SQLINTEGER    native_error ;
  SQLINTEGER    oldstatus;
  SQLINTEGER    newstatus = 0;

  /* If the table has been subscribed to through XLA, unsubscribe it. */

  if (SYSTEM_TABLE_ID != 0) {
    rc = ttXlaTableStatus(xla_handle, SYSTEM_TABLE_ID, 0,
                          &oldstatus, &newstatus);
    if (rc != SQL_SUCCESS) {
      handleXLAerror (rc, xla_handle, err_buf, &native_error);
      fprintf(stderr, "Error when unsubscribing from "TABLE_OWNER"."TABLE_NAME
              " table <%d>: %s", rc, err_buf);
    }
    SYSTEM_TABLE_ID = 0;
  }

  /* Close the XLA connection. */

  if (xla_handle != NULL) {
    rc = ttXlaClose(xla_handle);
    if (rc != SQL_SUCCESS) {
      fprintf(stderr, "Error when disconnecting from XLA:<%d>", rc);
    }
    xla_handle = NULL;
  }

  if (hstmt != SQL_NULL_HSTMT) {
```

```
      rc = SQLFreeStmt(hstmt, SQL_DROP);
      if (rc != SQL_SUCCESS) {
        handleError(rc, henv, hdbc, hstmt, err_buf, &native_error);
        fprintf(stderr, "Error when freeing statement handle:\n%s\n", err_buf);
      }
      hstmt = SQL_NULL_HSTMT;
    }

    /* Disconnect from TimesTen entirely. */

    if (hdbc != SQL_NULL_HDBC) {
      rc = SQLTransact(henv, hdbc, SQL_ROLLBACK);
      if (rc != SQL_SUCCESS) {
        handleError(rc, henv, hdbc, hstmt, err_buf, &native_error);
        fprintf(stderr, "Error when rolling back transaction:\n%s\n", err_buf);
      }

      rc = SQLDisconnect(hdbc);
      if (rc != SQL_SUCCESS) {
        handleError(rc, henv, hdbc, hstmt, err_buf, &native_error);
        fprintf(stderr, "Error when disconnecting from TimesTen:\n%s\n", err_buf);
      }

      rc = SQLFreeConnect(hdbc);
      if (rc != SQL_SUCCESS) {
        handleError(rc, henv, hdbc, hstmt, err_buf, &native_error);
        fprintf(stderr, "Error when freeing connection handle:\n%s\n", err_buf);
      }
      hdbc = SQL_NULL_HDBC;
    }

    if (henv != SQL_NULL_HENV) {
      rc = SQLFreeEnv(henv);
      if (rc != SQL_SUCCESS && rc != SQL_SUCCESS_WITH_INFO) {
        handleError(rc, henv, hdbc, hstmt, err_buf, &native_error);
        fprintf(stderr, "Error when freeing environment handle:\n%s\n", err_buf);
      }
      henv = SQL_NULL_HENV;
    }
    exit(status);
}
```

Using XLA as a replication mechanism

TimesTen replication as described in *Oracle TimesTen In-Memory Database Replication Guide* is sufficient for most customer needs; however, it is also possible to use XLA functions to replicate updates from one database to another. Implementing your own replication scheme on top of XLA in this way is fairly complicated, but can be considered if TimesTen replication is not feasible for some reason.

> **Note:** You cannot use XLA to replicate updates between different platforms or between 32-bit and 64-bit versions of the same platform.

In this section, the sending database is referred to as the master and the receiving database as the subscriber. To use XLA to replicate changes between databases, first use the ttXlaPersistOpen function to initialize the XLA handles, as described in "Initializing XLA and obtaining an XLA handle" on page 5-11.

After the XLA handles have been initialized for the databases, take the steps described in the following sections:

- Checking table compatibility between databases
- Replicating updates between databases
- Handling timeout and deadlock errors
- Checking for update conflicts

XLA functions mentioned here are documented in Chapter 9, "XLA Reference".

Checking table compatibility between databases

Before transferring update records from one database to the other, verify that the tables in the master and subscriber databases are compatible with one another:

- You can check the descriptions of a table and its columns by using the `ttXlaTableByName`, `ttXlaGetTableInfo`, and `ttXlaGetColumnInfo` functions. See "Checking table and column descriptions" immediately below.

- You can check the table and column versions of a specific XLA record by using the `ttXlaVersionTableInfo` and `ttXlaVersionColumnInfo` functions. See "Checking table and column versions" on page 5-35.

Checking table and column descriptions

Use the `ttXlaTableByName`, `ttXlaGetTableInfo`, and `ttXlaGetColumnInfo` functions to return `ttXlaTblDesc_t` and `ttXlaColDesc_t` descriptions for each table you want to replicate. These operations are described in "Specifying which tables to monitor for updates" on page 5-11 and "Obtaining column descriptions" on page 5-18. You can then pass these descriptions to the `ttXlaTableCheck` function. The output parameter, `compat`, specifies whether the tables are compatible. A value of 1 indicates compatibility and 0 indicates non-compatibility. The following example demonstrates this.

Example 5–18   Checking table and column descriptions for compatibility

```
SQLINTEGER compat;
ttXlaTblDesc_t table;
ttXlaColDesc_t columns[20];

rc = ttXlaTableCheck(xla_handle, &table, columns, &compat);
if (compat) {
    /* Go ahead and start replicating */
}
else {
    /* Not compatible or some other error occurred */
}
```

Checking table and column versions

Use the `ttXlaVersionTableInfo` and `ttXlaVersionColumnInfo` functions to retrieve the table structure information of an update record at the time the record was generated.

The following example verifies that the table associated with the *pXlaRecord* update record from the *pCmd* source is compatible with the *hXlaTarget* target.

Example 5–19   Checking table and column versions for compatibility

```
BOOL CUTLCheckXlaTable (SCOMMAND* pCmd,
                        ttXlaHandle_h hXlaTarget,
                        const ttXlaUpdateDesc_t* pXlaRecord)
{
  /* locals */
  ttXlaTblVerDesc_t tblVerDescSource;
  ttXlaColDesc_t colDescSource [255];
  SQLINTEGER iColsReturned = 0;
  SQLINTEGER iCompatible = 0;
  SQLRETURN rc;

  /* only certain update record types should be checked */
  if (pXlaRecord->type == INSERTTUP ||
      pXlaRecord->type == UPDATETUP ||
      pXlaRecord->type == DELETETUP)
  {
     /* Get source table description associated with this record */
     /* from the time it was generated. */
     rc = ttXlaVersionTableInfo (pCmd->pCtx->con->hXla,
             (ttXlaUpdateDesc_t*) pXlaRecord, &tblVerDescSource);

     if (rc == SQL_SUCCESS)
     {
         /* Get the source column descriptors for this table */
         /* at the time the record was generated. */
         rc = ttXlaVersionColumnInfo (pCmd->pCtx->con->hXla,
                 (ttXlaUpdateDesc_t*) pXlaRecord,
                 colDescSource, 255, &iColsReturned);

         if (rc == SQL_SUCCESS)
         {
             /* Check compatibility. */
             rc = ttXlaTableCheck (hXlaTarget,
                     &tblVerDescSource.tblDesc, colDescSource,
                     &iCompatible);
         }
     }
  }
}
```

Replicating updates between databases

When you are ready to begin replication, use the ttXlaNextUpdate or
ttXlaNextUpdateWait function to obtain batches of update records from the master
database and ttXlaApply to write the records to the subscriber database. The
following example shows this.

Example 5–20   Replicating updates between databases

```
int j;
ttXlaHandle_h h;
SQLINTEGER records;
ttXlaUpdateDesc_t** arry;

  do {
    /* get up to 15 updates */
    rc = ttXlaNextUpdate(h,&arry,15,&records);
    if (rc != SQL_SUCCESS) {
```

```
        /* See "Handling XLA errors" on page 5-28 */
    }

    /* print number of updates returned */
    printf("Records returned by ttXlaNextUpdate : %d\n",records);

    /* apply the received updates */
    for (j=0;j < records;j++) {
      ttXlaUpdateDesc_t* p;

      p = arry[j];
      rc = ttXlaApply(h, p, 0);
      if (rc != SQL_SUCCESS){
      /* See "Handling XLA errors" on page 5-28 and */
      /* "Handling timeout and deadlock errors" below */
      }
    }

    /* print number of updates applied */
    printf("Records applied successfully : %d\n",records);

} while (records != 0);
```

> **Important:** If you are packaging data to be replicated across a network, or anywhere between processes not using the same memory space, you must ensure that the ttXlaUpdateDesc_t data structure is shipped in its entirely. Its length is indicated by ttXlaUpdateDesc_t ->*header.length*, where the *header* element is a ttXlaNodeHdr_t structure that in turn has a *length* element. Also see "ttXlaUpdateDesc_t" on page 9-65 and "ttXlaNodeHdr_t" on page 9-64.

Handling timeout and deadlock errors

The return code from ttXlaApply indicates whether the update was successful. If the return code is not SQL_SUCCESS, then the update may have encountered a transient problem, such as a deadlock or timeout, or a persistent problem. You can use ttXlaError to check for errors, such as tt_ErrDeadlockVictim or tt_ErrTimeoutVictim. Recovery from transient errors is possible by rolling back the replicated transaction and reexecuting it. Other errors may be persistent, such as those for duplicate key violations or key not found. Such errors are likely to repeat if the transaction is reexecuted.

If ttXlaApply returns a timeout or deadlock error before applying the commit record (ttXlaUpdateDesc_t ->*flags* = TT_UPDCOMMIT) for a transaction to the subscriber database, you can do either of the following:

- Use ttXlaRollback to roll back the transaction.

- Use ttXlaCommit to commit the changes in the records that have been applied to the subscriber database.

To enable recovery from transient errors, you should keep track of transaction boundaries on the master database and store the records associated with the transaction currently being applied to the subscriber in a user buffer, so you can reapply them if necessary. The transaction boundaries can be found by checking the *flags* member of the ttXlaUpdateDesc_t structure. Consider the following example. If this condition is true, then the record was committed:

```
(pXlaRecords [iRecordIndex]->flags & TT_UPDCOMMIT)
```

If you encounter an error that requires you to roll back a transaction, call `ttXlaRollback` to roll back the records applied to the subscriber database. Then call `ttXlaApply` to reapply all the rolled back records stored in your buffer.

> **Note:** An alternative to buffering the transaction records in a user buffer is to call `ttXlaGetLSN` to get the transaction log record identifier of each commit record in the transaction log, as described in "Changing the location of a bookmark" on page 5-39. If you encounter an error that requires you to roll back a transaction, you can call `ttXlaSetLSN` to reset the bookmark to the beginning of the transaction in the transaction log and reapply the records. However, the extra overhead associated with the `ttXlaGetLSN` function may make this a less efficient option.

Checking for update conflicts

If you have applications making simultaneous updates to both your master and subscriber databases, you may encounter update conflicts. Update conflicts are described in detail in "Resolving Replication Conflicts" in *Oracle TimesTen In-Memory Database Replication Guide*.

To check for update conflicts in XLA, you can set the `ttXlaApply` *test* parameter to compare the old row value (`ttXlaUpdateDesc_t ->tuple1`) in each record of type `UPDATETUP` with the existing row in the subscriber database. If the old row value in the update description does not match the corresponding row in the subscriber database, an update conflict is probably the reason. In this case, `ttXlaApply` does not apply the update to the subscriber and returns an `sb_ErrXlaTupleMismatch` error.

Replicating updates to a non-TimesTen database

If you are replicating changes to a non-TimesTen database, you can use the `ttXlaGenerateSQL` function to convert the record data into a SQL statement that can be read by the non-TimesTen subscriber. For update and delete records, `ttXlaGenerateSQL` requires a primary key or a unique index on a non-nullable column to generate the correct SQL.

The `ttXlaGenerateSQL` function accepts a `ttXlaUpdateDesc_t` record as a parameter and outputs its SQL equivalent into a buffer.

> **Important:** The SQL returned by `ttXlaGenerateSQL` uses TimesTen SQL syntax. The SQL statement may fail on a non-TimesTen subscriber if there are SQL syntax incompatibilities between the two systems. In addition, the SQL statement is encoded in the connection character set associated with the XLA handle.

Example 5–21   Replicating updates to a non-TimesTen database

This example translates a record (`record`) and stores the resulting SQL output in a 200-character buffer (`buffer`). The actual size of the buffer is returned in the `actualLength` parameter.

```
ttXlaUpdateDesc_t record;
char buffer[200];
SQLINTEGER actualLength;
```

```
rc = ttXlaGenerateSQL(xla_handle, &record, buffer, 200, &actualLength);

if (rc != SQL_SUCCESS) {
    handleXLAerror (rc, xla_handle, err_buf, &native_error);
    if ( native_error == 8034 ) { // tt_ErrXlaNoSQL
      printf("Unable to translate to SQL\n");
    }
}
```

Other XLA features

The following sections describe how to use additional XLA features:

- Changing the location of a bookmark
- Passing application context

Changing the location of a bookmark

At any point during a connection, you can call the ttXlaGetLSN function to query the system for the Current Read log record identifier. If you must replay a set of updates, you can use the ttXlaSetLSN function to reset the Current Read log record identifier to any valid value larger than the Initial Read log record identifier set by the last ttXlaAcknowledge call. In this context, "larger" only applies if the log record identifiers being compared are from records in the same transaction. If that is not the case, then any log record identifier from a transaction that committed before another transaction is the "smaller" log record identifier, even if the numeric value of the log record identifier is larger. The only way to enable the Initial Read log record identifier to move forward to the Current Read log record identifier is by calling the ttXlaAcknowledge function, which indicates that you have received and processed all transaction log records up to the Current Read log record identifier. Once you have called ttXlaAcknowledge on a particular bookmark, you can no longer access transaction log records with a log record identifier smaller than the Current Read log record identifier.

Passing application context

Although it is not an XLA function, writers to the transaction log can call the ttApplicationContext built-in procedure to pass binary data associated with an application to XLA readers. This procedure specifies a single VARBINARY value that is returned in the next update record produced by the current transaction. XLA readers can obtain a pointer to this value as described in "Reading NOT INLINE variable-length column data" on page 5-20.

> **Note:** A context value will be applied to only one update record. After it has been applied it is reset. If the same context value should be applied to multiple updates, then it must be reestablished before each update.

To set the context:

1. Declare two program variables for invoking the ttApplicationContext procedure. The variable contextBuffer is a CHAR array that is declared to be large enough to accommodate the longest application context that you will use. The variable contextBufferLen is of type INTEGER and is used to convey the actual length of the context on each call to ttApplicationContext.

2. Initialize a statement handle with a compiled invocation of the `ttApplicationContext` built-in procedure:

```
rc = SQLPrepare(hstmt, "call ttApplicationContext(?)", SQL_NTS);
rc = SQLBindParameter(hstmt, 1, SQL_PARAM_INPUT, SQL_C_BINARY,
                          SQL_VARBINARY, 0, 0, &contextBuffer,
                          sizeof contextBuffer, &contextBufferLen);
```

3. When the application context must be set later, copy the context value into `contextBuffer`, assign the length of the context to `contextBufferLen`, and invoke `ttApplicationContext` with the call:

```
rc = SQLExecute(hstmt);
```

The transaction is then committed with the usual call on `SQLTransact`:

```
rc = SQLTransact(NULL, hdbc, SQL_COMMIT);
```

> **Note:** If a SQL operation fails after a call to `ttApplicationContext`, the context may not be stored in the next SQL operation and therefore may be lost. If this happens, the application can call `ttApplicationContext` again before the next SQL operation.

6

Distributed Transaction Processing: XA

This chapter describes the TimesTen implementation of the X/Open XA standard.

The TimesTen implementation of the XA interfaces is intended for use by transaction managers in distributed transaction processing (DTP) environments. You can use these interfaces to write a new transaction manager or to adapt an existing transaction manager, such as Oracle Tuxedo, to operate with TimesTen resource managers.

The purpose of this chapter is to provide information specific to the TimesTen implementation of XA and is intended to be used with the following documents:

- X/Open CAE Specification, *Distributed Transaction Processing: The XA Specification*, published by the The Open Group (`http://www3.opengroup.org`)

- Tuxedo documentation, available through the following location:

    `http://www.oracle.com/technetwork/middleware/weblogic/documentation`

This chapter includes the following topics:

- Overview of XA
- Using XA in TimesTen
- XA support through the Windows ODBC driver manager
- Configuring Tuxedo to use TimesTen XA

Important:

- The TimesTen XA implementation does not work with IMDB Cache. The start of any XA transaction will fail if the cache agent is running.

- You cannot execute an XA transaction if replication is enabled.

- Do not execute DDL statements within an XA transaction.

Overview of XA

This section provides a brief overview of the following XA concepts:

- X/Open DTP model
- Two-phase commit

X/Open DTP model

Figure 6–1 that follows illustrates the interfaces defined by the X/Open DTP model.

Figure 6–1 Distributed transaction processing model
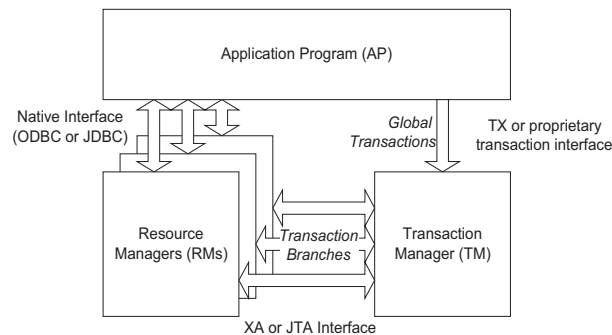

The TX interface is what applications use to communicate with a transaction manager. The figure shows an application communicating global transactions to the transaction manager. In the DTP model, the transaction manager breaks each global transaction down into multiple branches and distributes them to separate resource managers for service. It uses the XA interface to coordinate each transaction branch with the appropriate resource manager.

In the context of TimesTen XA, the resource managers can be a collection of TimesTen databases, or databases in combination with other commercial databases that support XA.

Global transaction control provided by the TX and XA interfaces is distinct from local transaction control provided by the native ODBC interface. It is generally best to maintain separate connections for local and global transactions. Applications can obtain a connection handle to a TimesTen resource manager in order to initiate both local and global transactions over the same connection. See "TimesTen tt_xa_context function to obtain ODBC handle from XA connection" on page 6-4 for more information.

Two-phase commit

In an XA implementation, the transaction manager commits the distributed branches of a global transaction by using a two-phase commit protocol.

1. In phase one, the transaction manager directs each resource manager to prepare to commit, which is to verify and guarantee it can commit its respective branch of the global transaction. If a resource manager cannot commit its branch, the transaction manager rolls back the entire transaction in phase two.

2. In phase two, the transaction manager either directs each resource manager to commit its branch or, if a resource manager reported it was unable to commit in phase one, rolls back the global transaction.

Note the following optimizations:

- If a global transaction is determined by the transaction manager to have involved only one branch, it skips phase one and commits the transaction in phase two.

- If a global transaction branch is read-only, where it does not generate any transaction log records, the transaction manager commits the branch in phase one and skips phase two for that branch.

> **Note:** The transaction manager considers the global transaction committed if and only if all branches successfully commit.

Using XA in TimesTen

The TimesTen implementation of XA provides an API that is consistent with the API specified in *Distributed Transaction Processing: The XA Specification*. This section describes what you should know when using the TimesTen implementation of XA, covering the following topics:

- TimesTen database requirements for XA
- Global transaction recovery in TimesTen
- Considerations in using standard XA functions with TimesTen
- TimesTen tt_xa_context function to obtain ODBC handle from XA connection
- Considerations in calling ODBC functions over XA connections in TimesTen
- XA resource manager switch
- XA error handling in TimesTen

TimesTen database requirements for XA

To guarantee global transaction consistency, TimesTen XA transaction branches must be durable. The TimesTen implementation of the `xa_prepare()`, `xa_rollback()`, and `xa_commit()` functions log their actions to disk, regardless of the value set in the `DurableCommits` general connection attribute or by the `ttDurableCommit` built-in procedure. (The behavior is equivalent to what occurs with a setting of `DurableCommits=1`. See "DurableCommits" in *Oracle TimesTen In-Memory Database Reference* for related information.) If you must recover from a failure, both the resource manager and the TimesTen transaction manager have a consistent view of which transaction branches were active in a prepared state at the time of failure.

Global transaction recovery in TimesTen

When a database is loaded from disk to recover after a failure or unexpected termination, any global transactions that were prepared but not committed are left pending, or in doubt. Normal processing is not enabled until the disposition of all in-doubt transactions has been resolved.

After connection and recovery are complete, TimesTen checks for in-doubt transactions. If there are no in-doubt transactions, operation proceeds as normal. If there are in-doubt transactions, other connections may be created, but virtually all operations are prohibited on those connections until the in-doubt transactions are resolved. Any other ODBC or JDBC calls result in the following error:

```
Error 11035 - "In-doubt transactions awaiting resolution in recovery must be
resolved first"
```

The list of in-doubt transactions can be retrieved through the XA implementation of `xa_recover()`, then dealt with through the XA call `xa_commit()`, `xa_rollback()`, or `xa_forget()`, as appropriate. After all of the in-doubt transactions are cleared, operation proceeds normally.

This scheme should be adequate for systems that operate strictly under control of the transaction manager, since the first thing the transaction manager should do after connect is to call xa_recover().

If the transaction manager is unavailable or cannot resolve an in-doubt transaction, you can use the ttXactAdmin utility -HCommit or -HAbort option to independently commit or abort the individual transaction branches. Be aware, however, that these ttXactAdmin options require ADMIN privilege. See "ttXactAdmin" in *Oracle TimesTen In-Memory Database Reference*.

Considerations in using standard XA functions with TimesTen

This section describes some issues concerning the use of TimesTen XA functions, which are of interest if you are writing your own transaction manager.

xa_open()

The *xa_info* string used by xa_open() should be a connection string identical to that supplied to SQLDriverConnect, such as:

```
"DSN=DataStoreResource;UID=MyName"
```

XA limits the length of the string to 256 characters. See MAXINFOSIZE in the xa.h header file.

The xa_open() function automatically turns off autocommit when it opens an XA connection.

A connection opened with xa_open() must be closed with a call to xa_close().

> **Note:**   Any user, other than the instance administrator, who wishes to connect to TimesTen must be granted the CREATE SESSION privilege. Refer to "Access control for connections" on page 2-6.

xa_close()

The *xa_info* string used by xa_close() should be empty.

Transaction id (XID) parameter

XA uniquely identifies global transactions by using a transaction ID, referred to as an *XID*. The XID is a required parameter for XA functions that manipulate a transaction. Internally, TimesTen maps XIDs to its own transaction identifiers.

The XID defined by the XA standard has some of its members (such as formatID, gtrid_length, and bqual_length) defined as type long. Be aware that this can cause problems when 32-bit client applications connect to a 64-bit server, or 64-bit client applications connect to a 32-bit server. This is because long is a 32-bit integer on 32-bit platforms but a 64-bit integer on 64-bit platforms, other than 64-bit Windows. Hence, TimesTen internally uses only the 32 least significant bits of those XID members regardless of the platform type of client or server. TimesTen does not support any value in those XID members that does not fit in a 32-bit integer.

TimesTen tt_xa_context function to obtain ODBC handle from XA connection

TimesTen provides the function tt_xa_context(), which enables you to acquire the ODBC connection handle associated with an XA connection opened by xa_open().

Syntax

```
#include <tt_xa.h>
int tt_xa_context(int* rmid, SQLHENV* henv, SQLHDBC* hdbc);
```

Parameters

Parameter	Type	Description
rmid	int	The specified resource manager ID
		If this is non-null, the function returns the handles associated with the *rmid* value.
		If the specified *rmid* is null, the function returns the handles associated with the first connection on this thread. For example, specify a null value if the connection has been opened outside the scope of the user-written code, where *rmid* is unknown. This establishes context in the application environment.
henv	out SQLHENV	The environment handle associated with the current xa_open() context
hdbc	out SQLHDBC	The connection handle associated with the current xa_open() context

Return values

0: Success

1: *rmid* not found

-1: Invalid parameter

Example

In the following example, assume Tuxedo has used xa_open() and xa_start() to open a connection to the database and start a transaction. To do further ODBC processing on the connection, use the tt_xa_context() function to locate the SQLHENV and SQLHDBC handles allocated by xa_open().

Example 6–1   Using tt_xa_context() to locate handles

```
do_insert()
{

    SQLHENV henv;
    SQLHDBC hdbc;
    SQLHSTMT hstmt;

    /* retrieve the handles for the current connection */
    tt_xa_context(NULL, &henv, &hdbc);

    /* now we can do our ODBC programming as usual */
    SQLAllocStmt(hdbc, &hstmt);

    SQLExecDirect(hstmt, "insert into t1 values (1)", SQL_NTS);

    SQLFreeStmt(hstmt, SQL_DROP);
}
```

Considerations in calling ODBC functions over XA connections in TimesTen

This section describes some TimesTen issues to be aware of when calling ODBC functions using an ODBC handle associated with an XA connection opened by `xa_open()`.

Autocommit

To simplify operation and prevent possible contradictions, `xa_open()` automatically turns off autocommit when it opens an XA connection.

Autocommit may subsequently be turned on or off during local transaction work, but must be turned off before `xa_start()` is called to begin work on a global transaction branch. If autocommit is on, a call to `xa_start()` returns the following error:

```
Error 11030 - "Autocommit must be turned off when working on global (XA)
transactions"
```

Once `xa_start()` has been called to begin work on a global transaction branch, autocommit may not be turned on until such work has been completed through a call to `xa_end()`. Any attempt to turn on autocommit in this case will result in the same error as above.

Local transaction COMMIT and ROLLBACK

Once work on a global transaction branch has commenced through a call to `xa_start()`, attempts to perform a local commit or rollback using `SQLTransact` results in the following error:

```
Error 11031 - "Illegal combination of local transaction and global (XA)
transaction"
```

Closing open cursors

Any open statement cursors must be closed using `SQLFreeStmt` with a value of `SQL_CLOSE` before calling `xa_end()` to end work on a global transaction branch. Otherwise, the following error is returned:

```
Error 11032 - "XA request failed due to open cursors"
```

XA resource manager switch

Each resource manager defines a switch in its `xa.h` header file that provides the transaction manager with access to the XA functions in the resource managers. The transaction manager never directly calls an XA interface function. Instead, it calls the function in the switch table, which, in turn, points to the appropriate function in the resource manager. This enables resource managers to be added and removed without the requirement to recompile the applications.

In the TimesTen implementation of XA, the functions in the XA switch, `xa_switch_t`, point to their respective functions defined in a TimesTen switch, `tt_xa_switch`.

xa_switch_t

The `xa_switch_t` structure defined by the XA specification is as follows:

```
/* XA Switch Data Structure */
#define RMNAMESZ        32         /* length of resource manager name, */
                                   /* including the null terminator */
#define MAXINFOSIZE     256        /* maximum size in bytes of xa_info strings, */
                                   /* including the null terminator */
```

```
struct xa_switch_t
{

    char name[RMNAMESZ];                 /* name of resource manager */
    long flags;                          /* resource manager specific options */
    long version;                        /* must be 0 */

int (*xa_open_entry)(char*, int, long);        /* xa_open function pointer */
int (*xa_close_entry)(char*, int, long);       /* xa_close function pointer*/
int (*xa_start_entry)(XID*, int, long);        /* xa_start function pointer */
int (*xa_end_entry)(XID*, int, long);          /* xa_end function pointer */
int (*xa_rollback_entry)(XID*, int, long);     /* xa_rollback function pointer */
int (*xa_prepare_entry)(XID*, int, long);      /* xa_prepare function pointer */
int (*xa_commit_entry)(XID*, int, long);       /* xa_commit function pointer */
int (*xa_recover_entry)(XID*, long, int, long); /* xa_recover function pointer*/
int (*xa_forget_entry)(XID*, int, long);        /* xa_forget function pointer */
int (*xa_complete_entry)(int*, int*, int, long); /* xa_complete function pointer
*/
};

typedef struct xa_switch_t xa_switch_t;
/*
 * Flag definitions for the RM switch
 */
#define TMNOFLAGS 0x00000000L     /* no resource manager features selected */
#define TMREGISTER 0x00000001L    /* resource manager dynamically registers */
#define TMNOMIGRATE 0x00000002L   /* RM does not support association migration */
#define TMUSEASYNC 0x00000004L    /* RM supports asynchronous operations */
```

tt_xa_switch

The `tt_xa_switch` names the actual functions implemented by a TimesTen resource
manager. It also indicates explicitly that association migration is not supported. In
addition, dynamic registration and asynchronous operations are not supported.

```
struct xa_switch_t
tt_xa_switch =
{
    "TimesTen", /* name of resource manager */
    TMNOMIGRATE, /* RM does not support association migration */
    0,
    tt_xa_open,
    tt_xa_close,
    tt_xa_start,
    tt_xa_end,
    tt_xa_rollback,
    tt_xa_prepare,
    tt_xa_commit,
    tt_xa_recover,
    tt_xa_forget,
    tt_xa_complete
};
```

XA error handling in TimesTen

The XA specification has a limited and strictly defined set of errors that can be
returned from XA interface calls. The ODBC `SQLError` function returns XA-defined
errors along with any additional information.

The TimesTen XA-related errors begin at number 11000. Errors 11002 through 11020 correspond to the errors defined by the XA standard.

See "Warnings and Errors" in *Oracle TimesTen In-Memory Database Error Messages and SNMP Traps* for the complete list of errors.

XA support through the Windows ODBC driver manager

This section discusses issues and procedures for using XA with the Windows ODBC driver manager. (UNIX ODBC driver managers are not considered.)

Issues to consider

XA support through the ODBC driver manager requires special handling. There are two fundamental problems:

- The XA interface is not part of the defined ODBC interface. If the XA symbols are directly referenced in an application, it is not possible to link with only the driver manager library to resolve all the external references.

- By design, the driver manager determines which driver `.dll` file to load at connect time, when you call `SQLConnect` or `SQLDriverConnect`. XA dictates that the connection should be opened through `xa_open()`. But the correct `xa_open()` entry point cannot be located until the `.dll` is loaded during the connect operation itself.

Note that the driver manager objective of database portability is generally not applicable here, since each XA implementation is essentially proprietary. The primary benefit of driver manager support for XA-enabled applications is to enable TimesTen-specific applications to run transparently with either the TimesTen direct driver or the TimesTen Client/Server driver.

Linking to the TimesTen ODBC XA driver manager extension library

On Windows installations, TimesTen provides a driver manager extension library, `ttxadm1122.dll`, for XA functions. Applications can make XA calls directly, but must link in the extension library.

To link with the `ttxadm1122.dll` library, applications must include `ttxadm1122.lib` before `odbc32.lib` in their link line. For example:

```
# Link with the ODBC driver manager
appldm.exe:appl.obj
        $(CC) /Feappldm.exe appl.obj ttxadm1122.lib odbc32.lib
```

> **Note:** The XA driver manager extension is implemented only for 32-bit Windows applications.

Configuring Tuxedo to use TimesTen XA

To configure Tuxedo to use the TimesTen resource managers, perform the following tasks.

- Update the $TUXDIR/udataobj/RM file
- Build the Tuxedo transaction manager server
- Update the GROUPS section in the UBBCONFIG file
- Compile the servers

> **Important:** Though TimesTen XA has been demonstrated to work with the Oracle Tuxedo transaction manager, TimesTen cannot guarantee the operation of DTP software beyond the TimesTen implementation of XA.

> **Notes:**
>
> - The examples in this section use the direct driver. You can also use the client/server library or driver manager library with the XA extension library.
>
> - Information on configuring TimesTen for object-relational mapping frameworks and application servers, including Oracle WebLogic Application Server, is available in the TimesTen Quick Start. Click **J2EE and OR Mapping** under Configuration and Setup.

Update the $TUXDIR/udataobj/RM file

To integrate the TimesTen XA resource manager into the Oracle Tuxedo system, update the `$TUXDIR/udataobj/RM` file to identify the TimesTen resource manager, the name of the TimesTen resource manager switch (`tt_xa_switch`), and the name of the library for the resource manager.

On UNIX platforms, add the following:

```
TimesTen:tt_xa_switch:-Linstall_dir/lib -ltten
```

For example:

```
TimesTen:tt_xa_switch:-L/opt/TimesTen/giraffe/lib -ltten
```

On Windows platforms, add the following:

```
TimesTen;tt_xa_switch;install_dir\lib\ttdv1122.lib
```

For example:

```
TimesTen;tt_xa_switch;C:\TimesTen\giraffe\lib\ttdv1122.lib
```

> **Note:** The *install_dir* is the path to the TimesTen home directory.

Build the Tuxedo transaction manager server

Use the `buildtms` command to build a transaction manager server for the TimesTen resource manager. Then copy the `TMS_TT` file created by `buildtms` to the `$TUXDIR/bin` directory.

On UNIX platforms, the commands are the following:

```
buildtms -o TMS_TT -r TimesTen -v
cp TMS_TT $TUXDIR/bin
```

On Windows platforms, the commands are the following:

```
buildtms -o TMS_TT -r TimesTen -v
copy TMS_TT.exe %TUXDIR%\bin
```

Update the GROUPS section in the UBBCONFIG file

For TMSNAME, specify the TMS_TT file created by the buildtms command described in the preceding section.

```
TMSNAME=TMS_TT
```

Enter a line for each TimesTen resource manager that specifies a group name, followed by the LMID, GRPNO, and OPENINFO parameters. Your OPENINFO string should look like this:

```
OPENINFO="TimesTen:DSN=DSNname"
```

Where *DSNname* is the name of the database.

Note that on Windows, Tuxedo servers run as user SYSTEM. Add the UID general connection attribute to the OPENINFO string to specify a user other than SYSTEM:

```
OPENINFO="TimesTen:DSN=DSNname;UID=user"
```

Do not specify a CLOSEINFO parameter for any TimesTen resource manager.

Example 6–2 shows the portions of a UBBCONFIG file used to configure two TimesTen resource managers, GROUP1 and GROUP2.

Example 6–2   Configuring TimesTen resource managers

```
*RESOURCES
...
*MACHINES
...
ENGSERV LMID=simple
*GROUPS
DEFAULT: TMSNAME=TMS_TT TMSCOUNT=2
GROUP1
    LMID=simple GRPNO=1 OPENINFO="TimesTen:DSN=MyDSN1;UID=MyName"
GROUP2
    LMID=simple GRPNO=2 OPENINFO="TimesTen:DSN=MyDSN2;UID=MyName"
*SERVERS
DEFAULT:
    CLOPT="-A"
simpserv1 SRVGRP=GROUP1 SRVID=1
simpserv2 SRVGRP=GROUP2 SRVID=2

*SERVICES
TOUPPER
TOLOWER
```

Compile the servers

Set the CFLAGS environment variable to include the *install_dir*/include directory that contains the TimesTen include files. Then use the buildserver command to construct an Oracle Tuxedo ATMI server load module.

On UNIX platforms, enter the following.

```
export CFLAGS=-Iinstall_dir/
buildserver -o server -f server.c -r TimesTen -s SERVICE
```

On Windows platforms, enter the following.

```
set CFLAGS=-Iinstall_dir\
buildserver -o server -f server.c -r TimesTen -s SERVICE
```

> **Note:** The *install_dir* is the path to the TimesTen home directory.

Example 6–3 shows an example of how to use the `buildclient` command to construct the client module (`simpcl`) and the `buildserver` command to construct the two server modules described in the `UBBCONFIG` file in Example 6–2 above.

Example 6–3   Construct server modules

```
set CFLAGS=-IC:\TimesTen\giraffe\
buildclient -o simpcl -f simpcl.c

ODBC Application Tuning

This chapter describes how to tune an ODBC application to run optimally on a TimesTen database. See "TimesTen Database Performance Tuning" in *Oracle TimesTen In-Memory Database Operations Guide* for more general tuning tips.

This chapter includes the following topics:

- Bypass driver manager if appropriate
- Using arrays of parameters for batch execution
- Avoid excessive binds
- Avoid SQLGetData
- Avoid data type conversions
- Bulk fetch rows of TimesTen data

Bypass driver manager if appropriate

TimesTen permits ODBC applications that do not need some of the functionality provided by a driver manager to link without one. In particular, applications that do not need ODBC access to database systems other than TimesTen should omit the driver manager. This is done by linking the application directly with the TimesTen direct or client driver, as described in "Linking options" on page 1-1. The performance improvement will be significant.

> **Note:** It is permissible for some applications connected to a database to be linked with the driver manager, while others connected to the same database are direct-linked.

Using arrays of parameters for batch execution

You can improve performance by using groups, referred to as *batches*, of statement executions in your application.

The `SQLParamOptions` ODBC function enables an application to specify multiple values for the set of parameters assigned by `SQLBindParameter`. This is useful for processing the same SQL statement multiple times with various parameter values. For example, your application can specify multiple sets of values for the set of parameters associated with an `INSERT` statement, and then execute the `INSERT` statement once to perform all the insert operations.

TimesTen supports the use of `SQLParamOptions` with `INSERT`, `UPDATE`, `DELETE`, and `MERGE` statements, but not with `SELECT` statements. TimesTen recommends the following batch sizes for TimesTen 11*g* Release 2 (11.2.2):

- 256 for `INSERT` statements

- 31 for `UPDATE` statements

- 31 for `DELETE` statements

- 31 for `MERGE` statements

Table 7–1 provides a summary of `SQLParamOptions` arguments. Refer to ODBC API reference documentation for details.

Table 7–1   SQLParamOptions arguments

Argument	Type	Description
hstmt	SQLHSTMT	Statement handle
crow	SQLROWSETSIZE	Number of values for each parameter
pirow	SQLROWSETSIZE	Pointer to storage for the current row number

Assuming the *crow* value is greater than 1, the *rgbValue* argument of `SQLBindParameter` points to an array of parameter values and the *pcbValue* argument points to an array of lengths. (Also see "SQLBindParameter function" on page 2-12.)

Refer to the TimesTen Quick Start demo source file `bulkinsert.c` for a complete working example of batching. (Also, for programming in C++ with TTClasses, see `bulktest.cpp`.)

> **Note:**   When using `SQLParamOptions` with the TimesTen Client/Server driver, data-at-execution parameters are not supported. (An application can pass the value for a parameter either in the `SQLBindParameter` *rgbValue* buffer or with one or more calls to `SQLPutData`. Parameters whose data is passed with `SQLPutData` are known as *data-at-execution* parameters. These are commonly used to send data for `SQL_LONGVARBINARY` and `SQL_LONGVARCHAR` parameters and can be mixed with other parameters.)

Avoid excessive binds

The purpose of a `SQLBindCol` or `SQLBindParameter` call is to associate a type conversion and program buffer with a data column or parameter. For a given SQL statement, if the type conversion or memory buffer for a given data column or parameter is not going to change over repeated executions of the statement, it is better not to make repeated calls to `SQLBindCol` or `SQLBindParameter`. Simply prepare once and bind once to execute many times.

> **Note:**   A call to `SQLFreeStmt` with the `SQL_UNBIND` option unbinds all columns.

Avoid SQLGetData

`SQLGetData` can be used for fetching data without binding columns. This can sometimes have a negative impact on performance because applications have to issue

a `SQLGetData` ODBC call for every column of every row that is fetched. In contrast, using bound columns requires only one ODBC call for each fetched column. Further, the TimesTen ODBC driver is more highly optimized for the bound columns method of fetching data.

`SQLGetData` can be very useful, though, for doing piecewise fetches of data from long character or binary columns. (This is discussed with respect to LOBs in "Using the LOB piecewise data interface in ODBC" on page 2-24.)

Avoid data type conversions

TimesTen instruction paths are so short that even small delays due to data conversion can cause a relatively large percentage increase in transaction time. To avoid data type conversions:

- Match input argument types to expression types.

- Match the types of output buffers to the types of the fetched values.

- Match the connection character set to the database character set.

Bulk fetch rows of TimesTen data

TimesTen provides the `TT_PREFETCH_COUNT` option, which can be set through `SQLSetStmtOption` and enables an application to fetch multiple rows of data. This feature is available for applications that use the Read Committed isolation level. For applications that retrieve large amounts of TimesTen data, fetching multiple rows can increase performance greatly. However, locks are held on all rows being retrieved until the application has received all the data, decreasing concurrency. For more information on how to use `TT_PREFETCH_COUNT`, see "Prefetching multiple rows of data" on page 2-11.

8

TimesTen Utility API

The TimesTen Utility Library C language functions documented in this chapter provide a programmable interface to some of the command line utilities documented in "Utilities" in *Oracle TimesTen In-Memory Database Reference*.

Applications that use this set of C language functions must include `ttutillib.h` and link with both the TimesTen driver library (`libtten` on UNIX or `ttdv1122.lib` and `tten1122.lib` on Windows) and the TimesTen utility library (`libttutil` on UNIX and `ttutil1122.lib` on Windows platforms).

> **Important:** Applications must call the `ttUtilAllocEnv` C function before calling any other TimesTen utility library function. In addition, applications must call the `ttUtilFreeEnv` C function when done using the TimesTen utility library interface.

These functions are not supported with TimesTen Client or for Java applications. They are supported only for TimesTen ODBC applications using the direct driver.

Return codes

Unless otherwise indicated, the utility functions return these codes as defined in `ttutillib.h`.

Code	Description
TTUTIL_SUCCESS	Indicates success.
TTUTIL_ERROR	Indicates an error occurs.
TTUTIL_WARNING	Upon success, indicates a warning has been generated.
TTUTIL_INVALID_HANDLE	Indicates an invalid utility library handle is specified.

> **Note:** The application must call the `ttUtilGetError` C function to retrieve all actual error or warning information.

ttBackup

Description

Creates either a full or an incremental backup copy of the database specified by *connStr*. You can back up a database either to a set of files or to a stream. You can restore the database at a later time using either the ttRestore function or the ttRestore utility.

For an overview of the TimesTen backup and restore facility, see "Migration, Backup, and Restoration" in *Oracle TimesTen In-Memory Database Installation Guide*.

Required privilege

ADMIN

Syntax

```
ttBackup (ttUtilHandle handle, const char* connStr,
          ttBackUpType type, ttBooleanType atomic,
          const char* backupDir, const char* baseName,
          ttUtFileHandle stream)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying a connection string that describes the database to be backed up.

Parameter	Type	Description
type	ttBackupType	Specifies the type of backup to be performed. Valid values are as follows:

- `TT_BACKUP_FILE_FULL`: Performs a full file backup to the backup path specified by the *backupDir* and *baseName* parameters. The resulting backup is not enabled for incremental backup.

- `TT_BACKUP_FILE_FULL_ENABLE`: Performs a full file backup to the backup path specified by the *backupDir* and *baseName* parameters. The resulting backup is enabled for incremental backup.

- `TT_BACKUP_FILE_INCREMENTAL`: Performs an incremental file backup to the backup path specified by the *backupDir* and *baseName* parameters, if that backup path contains an incremental-enabled backup of the database. Otherwise, an error is returned.

- `TT_BACKUP_FILE_INCR_OR_FULL`: Performs an incremental file backup to the backup path specified by the *backupDir* and *baseName* parameters of that backup path contains an incremental-enabled backup of the database. Otherwise, it performs a full file backup of the database and marks it incremental enabled.

- `TT_BACKUP_STREAM_FULL`: Performs a stream backup to the stream specified by the *stream* parameter.

- `TT_BACKUP__INCREMENTAL_STOP`: Does not perform a backup. Disables incremental backups for the backup path specified by the *backupDir* and *baseName* parameters. This prevents transaction log files from accumulating for an incremental backup.

Parameter	Type	Description
atomic	ttBooleanType	Specifies the disposition of an existing backup with the same *baseName* and *backupDir* while the new backup is being created.
		This parameter has an effect only on full file backups when there is an existing backup with the same *baseName* and *backupDir*. It is ignored for incremental backups because they augment, rather than replace, an existing backup. It is ignored for stream backups because they write to the given stream, ignoring the *baseName* and *backupDir* parameters.
		The following are valid values:
		■ TT_FALSE: The existing backup is destroyed before the new backup begins. If the new backup fails to complete, neither the new, incomplete, backup nor the existing backup can be used to restore the database. This option should be used only when the database is being backed up for the first time, when there is a another backup of the database that uses a different *baseName* or *backupDir*, or when the application can tolerate a window of time (typically tens of minutes long for large databases) during which no backup of the database exists.
		■ TT_TRUE: The existing backup is destroyed only after the new backup has completed successfully. If the new backup fails to complete, the old backup is retained and can be used to restore the database. If there is an existing backup with the same *baseName* and *backupDir* then the use of this option ensures that there is no window of time during which neither the existing backup nor the new backup is available for restoring the database, and it ensures that the existing backup will be destroyed only if it has been successfully superseded by the new backup. However, it does require enough disk space for both the existing and new backups to reside in the *backupDir* at the same time.
backupDir	const char*	Specifies the backup directory for file backups. It is ignored for stream backups. Otherwise it must be non-null.
		For TT_BACKUP_INCREMENTAL_STOP, it specifies the directory portion of the backup path that is to be disabled.
		For TT_BACKUP_INCREMENTAL_STOP or a file backup, an error is returned if NULL is specified.

Parameter	Type	Description
baseName	const char*	Specifies the file prefix for the backup files in the backup directory specified by the *backupDir* parameter for file backups.
		It is ignored for stream backups.
		If NULL is specified for this parameter, the file prefix for the backup files is the file name portion of the DataStore attribute in the ODBC definition of the database.
		For TT_BACKUP_INCREMENTAL_STOP, this parameter specifies the basename portion of the backup path that is to be disabled.
stream	ttUtFileHandle	For stream backups, this parameter specifies the stream to which the backup is to be written.
		On UNIX, it is an integer file descriptor that can be written to by using write(2). Pass 1 to write the backup to stdout.
		On Windows, it is a handle that can be written to using WriteFile. Pass the result of GetStdHandle(STD_OUTPUT_HANDLE) to write the backup to the standard output.
		This parameter is ignored for file backups.
		The application can pass TTUTIL_INVALID_FILE_HANDLE for this parameter.

Example

This example backs up the database for the payroll DSN into C:\backup.

```
ttUtilHandle  utilHandle;
int           rc;
rc = ttBackup (utilHandle,  "DSN=payroll", TT_BACKUP_FILE_FULL,
     TT_TRUE, "c:\\backup", NULL, TTUTIL_INVALID_FILE_HANDLE);
```

Upon successful backup, all files are created in the C:\backup directory.

Note

Each database supports only eight incremental-enabled backups.

ttRestore
"ttBackup" and "ttRestore" utilities in *Oracle TimesTen In-Memory Database Reference*

ttDestroyDataStore

Description

Destroys a database, including all checkpoint files, transaction logs and daemon catalog entries corresponding to the database specified by the connection string. It does not delete the DSN itself defined in the sys.odbc.ini or user odbc.ini file on the supported UNIX platforms or in Windows registry on the supported Windows platforms.

Required privilege

Instance administrator

Syntax

```
ttDestroyDataStore (ttUtilHandle handle, const char* connStr,
                    unsigned int timeout)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying the connection string that describes the database to be destroyed. All attributes in this connection string, except the DSN and the DataStore attribute, are ignored.
timeout	unsigned int	Specifies the number of times to retry before returning to the caller. ttDestroyDataStore continually retries the destroy operation every second until it is successful or the timeout is reached. This is useful in those situations where the destroy fails due to some temporary condition, such as when the database is in use.
		No retry is performed if this parameter value is 0.

Example

This example destroys a database defined by the payroll DSN, consisting of files C:\dsns\payroll.ds0, C:\dsns\payroll.ds1, and several transaction log files C:\dsns\payroll.logn.

```
char          errBuff [256];
int           rc;
unsigned int  retCode;
ttUtilErrType retType;
ttUtilHandle  utilHandle;
...
...
rc = ttDestroyDataStore (utilHandle, "DSN=payroll", 30);
if (rc == TTUTIL_SUCCESS)
   printf ("Datastore payroll successfully destroyed.\n");
else if (rc == TTUTIL_INVALID_HANDLE)
```

```
       printf ("TimesTen utility library handle is invalid.\n");
else
  while ((rc = ttUtilGetError (utilHandle, 0, &retCode,
            &retType, errBuff, sizeof (errBuff), NULL)) !=
            TTUTIL_NODATA)
    {
  ...
  ...
}
```

ttDestroyDataStoreForce

Description

Destroys a database, including all checkpoint files, transaction logs and daemon catalog entries corresponding to the database specified by the connection string. It does not delete the DSN itself defined in the sys.odbc.ini or user odbc.ini file on the supported UNIX platforms or in the Windows registry on supported Windows platforms.

Required privilege

Instance administrator

Syntax

```
ttDestroyDataStoreForce (ttUtilHandle handle, const char* connstr,
                         unsigned int timeout)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying the connection string that describes the database to be destroyed. All attributes in this connection string, except the DSN and the DataStore attribute, are ignored.
timeout	unsigned int	Specifies the number of seconds to retry before returning to the caller. The ttDestroyDataStoreForce utility continually retries the destroy operation every second until it is successful or the timeout is reached. This is useful when the destroy fails due to some temporary condition, such as when the database is in use.
		No retry is performed if this parameter value is 0.

Example

This example destroys a database defined by the payroll DSN, consisting of files C:\dsns\payroll.ds0, C:\dsns\payroll.ds1, and several transaction log files C:\dsns\payroll.log*n*.

```
char            errBuff [256];
int             rc;
unsigned int    retCode;
ttUtilErrType   retType;
ttUtilHandle    utilHandle;
...
...
rc = ttDestroyDataStoreForce (utilHandle, "DSN=payroll", 30);
if (rc == TTUTIL_SUCCESS)
  printf ("Datastore payroll successfully destroyed.\n");
else if (rc == TTUTIL_INVALID_HANDLE)
```

```
      printf ("TimesTen utility library handle is invalid.\n");
else
   while ((rc = ttUtilGetError (utilHandle, 0, &retCode,
                                &retType, errBuff, sizeof (errBuff), NULL)) !=
                                TTUTIL_NODATA)
     {
   ...
   ...
}
```

ttRamGrace

Description

Specifies the number of seconds the database specified by the connection string is kept in RAM by TimesTen after the last application disconnects from the database. TimesTen then unloads the database. This grace period can be set or reset at any time but is only in effect if the RAM policy is TT_RAMPOL_INUSE.

Required privilege

Instance administrator

Syntax

```
ttRamGrace (ttUtilHandle handle, const char* connStr, unsigned int seconds)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying a connection string that describes the database for which the RAM grace period is set.
seconds	unsigned int	Specifies the number of seconds TimesTen keeps the database in RAM after the last application disconnects from the database. TimesTen then unloads the database.

Example

This example sets the RAM grace period of 10 seconds for the payroll DSN.

```
ttUtilHandle    utilHandle;
int             rc;
rc = ttRamGrace (utilHandle, "DSN=payroll", 10);
```

See also

ttRamLoad
ttRamPolicy
ttRamUnload

ttRamLoad

Description

Causes TimesTen to load the database specified by the connection string into the system RAM. For a permanent database, a call to ttRamLoad is valid only when RamPolicy is set to TT_RAMPOL_MANUAL. For a temporary database, a call to ttRamLoad loads the database into RAM.

Refer to "ttRamPolicySet" in *Oracle TimesTen In-Memory Database Reference* or to ttRamPolicy for related information.

Required privilege

Instance administrator

Syntax

```
ttRamLoad (ttUtilHandle handle, const char* connStr)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying a connection string that describes the database to be loaded into RAM.

Example

This example loads the database for the payroll DSN.

```
ttUtilHandle   utilHandle;
int            rc;
rc = ttRamLoad (utilHandle, "DSN=payroll");
```

See also

ttRamGrace
ttRamPolicy
ttRamUnload

ttRamPolicy

Description

Defines the policy used to determine when TimesTen loads the database specified by the connection string into the system RAM.

Required privilege

Instance administrator

Syntax

```
ttRamPolicy (ttUtilHandle handle, const char* connStr,
             ttRamPolicyType policy)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying a connection string that describes the database for which the RAM policy is to be set.
policy	ttRamPolicyType	Specifies the policy used to determine when TimesTen loads the specified database into system RAM. Valid values are the following: ■ TT_RAMPOL_ALWAYS: Specifies that the database should always remain in RAM. ■ TT_RAMPOL_MANUAL: Specifies that the database can be loaded into RAM explicitly using either the ttRamLoad C function or the ttAdmin -ramLoad command. Similarly, the database can be unloaded from RAM explicitly by using ttRamUnload C function or using ttAdmin -ramUnload command. ■ TT_RAMPOL_INUSE: Specifies that the database is to be loaded into RAM when an application wants to connect to the database. This RAM policy may be further modified using the ttRamGrace C function or using the ttAdmin -ramGrace command. If you do not explicitly set the RAM policy for the specified database, the default RAM policy is TT_RAMPOL_INUSE.

Example

This example sets the RAM policy to manual for the payroll DSN.

```
ttUtilHandle    utilHandle;
int             rc;
rc = ttRamPolicy (utilHandle, "DSN=payroll", TT_RAMPOL_MANUAL);
```

Note

The policy cannot be set for a temporary database.

See also

ttRamGrace
ttRamLoad
ttRamUnload

ttRamUnload

Description

Causes TimesTen to unload the database specified by the connection string from the system RAM if the TimesTen RAM policy is set to manual. For a permanent database, this call is valid only when RAM policy is set to TT_RAMPOL_MANUAL. For a temporary database, a call to ttRamUnload always tries to unload the database from RAM because RAM policy cannot be set for such a database.

Refer to "ttRamPolicySet" in *Oracle TimesTen In-Memory Database Reference* or to ttRamPolicy for related information.

Required privilege

Instance administrator

Syntax

```
ttRamUnload (ttUtilHandle handle, const char* connStr)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying a connection string for the database to be unloaded from RAM.

Example

This example unloads the database from RAM for the payroll DSN.

```
ttUtilHandle    utilHandle;
int             rc;
rc = ttRamUnload (utilHandle, "DSN=payroll");
```

Notes

When using this function with a temporary database, TimesTen always attempts to unload the database.

ttRamGrace
ttRamLoad
ttRamPolicy

ttRepDuplicateEx

Description

Creates a replica of a remote database on the local system. The process is initiated from the receiving local system. From there, a connection is made to the remote source database to perform the duplicate operation.

> **Notes:**
>
> - This utility has features to recover from a site failure by creating a disaster recovery (DR) read-only subscriber as part of the active standby pair replication scheme. See "Using a disaster recovery subscriber in an active standby pair" in *Oracle TimesTen In-Memory Database Replication Guide* for additional information.
>
> - If the database does not use cache groups, the following items discussed below are not relevant: `cacheuid` and `cachepwd` data structure elements; `TT_REPDUP_NOKEEPCG`, `TT_REPDUP_RECOVERINGNODE`, `TT_REPDUP_INITCACHEDR`, and `TT_REPDUP_DEFERCACHEUPDATE` flag values.
>
> - There are elements in the `ttRepDuplicateExArg` structure that is a parameter of this utility, *localIP* and *remoteIP*, that allow you to optionally specify which local network interface to use, which remote network interface to use, or both.

Required privilege

Requires an instance administrator on the receiving local database (where `ttRepDuplicateEx` is called) and a user with `ADMIN` privilege on the remote source database. Create the internal user on the remote source store as necessary.

In addition, be aware of the following requirements to execute `ttRepDuplicateEx`:

- The operating system user name of the instance administrator on the receiving local database must be the same as the operating system user name of the instance administrator on the remote source database.

- When `ttRepDuplicateEx` is called, the `uid` and `pwd` data structure elements must specify the user name and password of the user with `ADMIN` privilege on the remote source database. This user name is used to connect to the remote source database to perform the duplicate operation.

Syntax

```
ttRepDuplicateEx (ttUtilHandle handle,
                  const char* destConnStr,
                  const char* srcDatabase,
                  const char* remoteHost,
                  ttRepDuplicateExArg* arg
                  )
typedef struct
{
     unsigned int size; /*set to size of(ttRepDuplicateExArg) */
     unsigned int flags;
     const char* uid;
```

```
            const char* pwd;
            const char* pwdcrypt;
            const char* cacheuid;
            const char* cachepwd;
            const char* localHost;
            int truncListLen;
            const char** truncList;
            int dropListLen;
            const char** dropList;
            int maxbytesPerSec;
            int remoteDaemonPort;
            int nThreads4initDR;
            const char* localIP
            const char* remoteIP
            int crsManaged;
            /*new struct elements can only be added here at the end */
    } ttRepDuplicateExArg
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
destConnStr	const char*	This is a null-terminated string specifying the connection string for a local database into which the replica of the remote database is created.
srcDatabase	const char*	This is a null-terminated string specifying the remote source database name. This name is the last component of the database path name.
remoteHost	const char*	This is a null-terminated string specifying the TCP/IP host name of the system where the remote source database is located.
arg	ttRepDuplicateExArg*	This is the address of the structure containing the desired ttRepDuplicateEx arguments. If NULL is passed in for *arg* or if the value of *arg* ->*size* is invalid, TimesTen returns error 12230, "Invalid argument value", and TTUTIL_ERROR.

Struct elements

The ttRepDuplicateExArg structure contains these elements:

Element	Type	Description
size	unsigned int	Size This must be set up to *sizeof* (ttRepDuplicateExArg).
flags	unsigned int	Bit-wise union of values chosen from the list in the table of flag values

Element	Type	Description
uid	const char*	User name of a user on the remote source database with ADMIN privileges This user name is used to connect to the remote source database to perform the duplicate operation.
pwd	const char*	Password associated with the user ID
pwdcrypt	const char*	Encrypted password associated with the user ID
cacheuid	const char*	Cache administration user ID
cachepwd	const char*	Cache administration user password
localHost	const char*	Null-terminated string specifying the TCP/IP host name of the local system This element is ignored if *remoteRepStart* is TT_FALSE. This explicitly identifies the local host. This parameter can be null, which is useful if the local host uses a nonstandard name such as an IP address.
truncListLen	int	Number of elements in the *truncList*
truncList	const char**	List of non-replicated tables to truncate after duplicate
dropListLen	int	Number of elements in *dropList*
dropList	const char**	List of non-replicated tables to drop after the duplicate operation
maxbytesPerSec	int	Maximum kilobytes per second Setting this to a nonzero value specifies that the duplicate operation should not put more than *maxbytesPerSec* kilobytes of data per second onto the network. Setting it to 0 or a negative number indicates that the duplicate operation should not attempt to limit its bandwidth.
remoteDaemonPort	int	Remote daemon port Setting this to 0 results in the daemon port number for the target database being set to the port number used for the daemon on the source database. This option cannot be used in duplicate operations for databases with automatic port configuration.
nThreads4initDR	int	Number of threads for initialization For the disaster recovery subscriber, this determines the number of threads used to initialize the Oracle database on the disaster recovery site. After the TimesTen database is copied to the disaster recovery system, the Oracle database tables are truncated and the data from the TimesTen cache groups is copied to the Oracle database on the disaster recovery system. Also see the TT_REPDUP_INITCACHEDR flag below.

Element	Type	Description
localIP	const char*	A null-terminated string specifying the alias or IP address (IPv4 or IPv6) of the local network interface to use for the duplicate operation. Set this to NULL if you do not want to specify the local network interface, in which case any compatible interface may be used.
remoteIP	const char*	A null-terminated string specifying the alias or IP address (IPv4 or IPv6) of the remote network interface to use for the duplicate operation. Set this to NULL if you do not want to specify the remote network interface, in which case any compatible interface may be used. **Note**: You can specify both *localIP* and *remoteIP*, or either one by itself, or neither.
crsManaged	int	For internal use. This should be set to 0 (default).

The ttRepDuplicateExArg *flags* element is constructed from these values:

Value	Description
TT_REPDUP_NOFLAGS	Indicates no flags.
TT_REPDUP_COMPRESS	Enables compression of the data transmitted over the network for the duplicate operation.
TT_REPDUP_REPSTART	Directs ttRepDuplicateEx to set the replication state (with respect to the local database) in the remote database to the start state before the remote database is copied across the network. This ensures that all updates made after the duplicate operation are replicated from the remote database to the newly created or restored local database.
TT_REPDUP_RAMLOAD	Keeps the database in memory upon completion of the duplicate operation. It changes the RAM policy for the database to manual.
TT_REPDUP_DELXLA	Directs ttRepDuplicateEx to remove all the XLA bookmarks as part of the duplicate operation.
TT_REPDUP_NOKEEPCG	Do not preserve the cache group definitions; ttRepDuplicateEx converts all cache group tables into regular tables. By default, cache group definitions are preserved.

Value	Description
TT_REPDUP_RECOVERINGNODE	Specifies that ttRepDuplicateEx is being used to recover a failed node for a replication scheme that has an AWT or autorefresh cache group. Do not specify TT_REPDUP_RECOVERINGNODE when rolling out a new or modified replication scheme to a node. If ttRepDuplicateEx cannot update metadata stored on the Oracle database and all incremental autorefresh cache groups are replicated, then updates to the metadata will be automatically deferred until the cache and replication agents are started.
TT_REPDUP_DEFERCACHEUPDATE	Forces the deferral of changes to metadata stored on the Oracle database until the cache and replication agents are started and the agents can connect to the Oracle database. Using this option can cause a full autorefresh if some incremental cache groups are not replicated or if ttRepDuplicateEx is being used for rolling out a new or modified replication scheme to a node.
TT_REPDUP_INITCACHEDR	Initializes disaster recovery. You must also specify *cacheuid* and *cachepwd* in the data structure. Also see *nThreads4initDR* in the data structure.

Example

This example creates a replica of a remote TimesTen DSN, remote_payroll with the database path name C:\dsns\payroll, to a local DSN local_payroll.

```
ttUtilHandle utilHandle;
int rc;
ttRepDuplicateExArg arg;

memset(&arg, 0, sizeof(arg));
arg.size = sizeof(ttRepDuplicateExArg);
arg.flags = TT_REPDUP_REPSTART | TT_REPDUP_DELXLA;
arg.localHost = "mylocalhost";
arg.uid="myuid";
arg.pwd="mypwd";
rc=ttRepDuplicateEx(utilHandle,"DSN=local_payroll","payroll","remotehost", &arg);
```

```
ttReplicationStatus
ttRepPolicySet
ttRepStop
ttRepSubscriberStateSet
ttRepSyncGet
ttRepSyncSet
```

ttRestore

Description

Restores a database specified by the connection string from a backup that has been created using the ttBackup C function or ttBackup utility. If the database already exists, ttRestore will not overwrite it.

For an overview of the TimesTen backup and restore facility, see "Migration, Backup, and Restoration" in *Oracle TimesTen In-Memory Database Installation Guide*.

Required privilege

Instance administrator

Syntax

```
ttRestore (ttUtilHandle handle, const char* connStr,
           ttRestoreType type, const char* backupDir,
           const char* baseName, ttUtFileHandle stream,
           unsigned intflags)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char*	This is a null-terminated string specifying a connection string that describes the database to be restored.
type	ttRestoreType	Indicates whether the database is to be restored from a file or a stream backup. Valid values are the following: ■ TT_RESTORE_FILE: The database is to be restored from a file backup located at the backup path specified by the backupDir and baseName parameters. ■ TT_RESTORE_STREAM: The database is to be restored from a stream backup read from the given stream.
backupDir	const char*	For TT_RESTORE_FILE, specifies the directory where the backup files are stored. For TT_RESTORE_STREAM, this parameter is ignored.
baseName	const char*	For TT_RESTORE_FILE, specifies the file prefix for the backup files in the backup directory specified by the backupDir parameter. If NULL is specified, the file prefix for the backup files is the file name portion of the DataStore attribute of the database ODBC definition. For TT_RESTORE_STREAM, this parameter is ignored.

Parameter	Type	Description
stream	ttUtFileHandle	For `TT_RESTORE_STREAM`, specifies the stream from which the backup is to be read.
		On UNIX, it is an integer file descriptor that can be read from using `read(2)`. Pass 0 to read the backup from `stdin`.
		On Windows, it is a handle that can be read from using `ReadFile`. Pass the result of `GetStdHandle(STD_INPUT_HANDLE)` to read from the standard input.
		For `TT_RESTORE_FILE`, this parameter is ignored. The application can pass `TTUTIL_INVALID_FILE_HANDLE` for this parameter.
flags	unsigned int	This is reserved for future use. Set it to 0.

Example

This example restores the database for the `payroll` DSN from `C:\backup`.

```
ttUtilHandle    utilHandle;
int             rc;

rc = ttRestore (utilHandle, "DSN=payroll", TT_RESTORE_FILE,
                "c:\\backup", NULL, TTUTIL_INVALID_FILE_HANDLE, 0);
```

ttBackup
"ttBackup" and "ttRestore" utilities in *Oracle TimesTen In-Memory Database Reference*

ttUtilAllocEnv

Description

Allocates memory for a TimesTen utility library environment handle and initializes the TimesTen utility library interface for use by an application. An application must call ttUtilAllocEnv before calling any other TimesTen utility library function. In addition, an application should call ttUtilFreeEnv when it is done using the TimesTen utility library interface.

Required privilege

None

Syntax

```
ttUtilAllocEnv (ttUtilHandle* handle_ptr, char* errBuff,
                unsigned int buffLen, unsigned int* errLen)
```

Parameters

Parameter	Type	Description
handle_ptr	ttUtilHandle*	Specifies a pointer to storage where the TimesTen utility library environment handle is returned.
errBuff	char*	This is a user allocated buffer where error messages (if any) are returned. The returned error message is a null-terminated string. If the length of the error message exceeds *buffLen*-1, it is truncated to *buffLen*-1. If this parameter is null, *buffLen* is ignored and TimesTen does not return error messages to the calling application.
buffLen	unsigned int	Specifies the size of the buffer *errBuff*. If this parameter is 0, TimesTen does not return error messages to the calling application.
errLen	unsigned int*	This is a pointer to an unsigned integer where the actual length of the error message is returned. If it is NULL, this parameter is ignored.

Return codes

This utility returns the following code as defined in ttutillib.h.

Code	Description
TTUTIL_SUCCESS	Returned upon success.

Otherwise, it returns a TimesTen-specific error message as defined in tt_errCode.h and a corresponding error message in the buffer provided by the caller.

Example

This example allocates and initializes a TimesTen utility library environment handle with the name utilHandle.

```
char        errBuff [256];
```

```
int         rc;
ttUtilHandle  utilHandle;

rc = ttUtilAllocEnv (&utilHandle, errBuff, sizeof(errBuff), NULL);
```

See also

ttUtilFreeEnv
ttUtilGetError
ttUtilGetErrorCount

ttUtilFreeEnv

Description

Frees memory associated with the TimesTen utility library handle.

An application must call ttUtilAllocEnv before calling any other TimesTen utility library function. In addition, an application should call ttUtilFreeEnv when it is done using the TimesTen utility library interface.

Required privilege

None

Syntax

```
ttUtilFreeEnv (ttUtilHandle handle, char* errBuff,
               unsigned int buffLen, unsigned int* errLen)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
errBuff	char*	This is a user-allocated buffer where error messages are to be returned. The returned error message is a null-terminated string. If the length of the error message exceeds *buffLen*-1, it is truncated to *buffLen*-1. If this parameter is NULL, *buffLen* is ignored and TimesTen does not return error messages to the calling application.
buffLen	unsigned int	Specifies the size of the buffer *errBuff*. If this parameter is 0, TimesTen does not return error messages to the calling application.
errLen	unsigned int*	This is a pointer to an unsigned integer where the actual length of the error message is returned. If it is NULL, this parameter is ignored.

Return codes

This utility returns the following codes as defined in ttutillib.h.

Code	Description
TTUTIL_SUCCESS	Returned upon success.
TTUTIL_INVALID_HANDLE	Returned if an invalid utility library handle is specified.

Otherwise, it returns a TimesTen-specific error message as defined in tt_errCode.h and a corresponding error message in the buffer provided by the caller.

Example

This example frees a TimesTen utility library environment handle named utilHandle.

```
char          errBuff [256];
```

```
int          rc;
ttUtilHandle  utilHandle;

rc = ttUtilFreeEnv (utilHandle, errBuff, sizeof(errBuff), NULL);
```

See also

ttUtilAllocEnv
ttUtilGetError
ttUtilGetErrorCount

ttUtilGetError

Description

Retrieves the errors and warnings generated by the last call to the TimesTen C utility library functions excluding ttUtilAllocEnv and ttUtilFreeEnv.

Required privilege

None

Syntax

```
ttUtilGetError (ttUtilHandle handle, unsigned int errIndex,
                unsigned int* retCode, ttUtilErrType* retType,
                char* errbuff, unsigned int buffLen,
                unsigned int* errLen)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
errIndex	unsigned int	Indicates error or warning record to be retrieved from the TimesTen utility library error array. Valid values are as follows: ■ 0: Retrieve the next record from the utility library error array. ■ 1...*n*: Retrieve the specified record from the utility library error array, where *n* is the error count returned by the ttUtilGetErrorCount call.
retCode	unsigned int*	Returns the TimesTen-specific error or warning codes as defined in tt_errCode.h.
retType	ttUtilErrType*	Indicates whether the returned message is an error or warning. The following are valid return values: ■ TTUTIL_ERROR ■ TTUTIL_WARNING
errBuff	char*	This is a user allocated buffer where error messages (if any) are to be returned. The returned error message is a null-terminated string. If the length of the error message exceeds *buffLen*-1, it is truncated to *buffLen*-1. If this parameter is NULL, *buffLen* is ignored and TimesTen does not return error messages to the calling application.
buffLen	unsigned int	Specifies the size of the buffer *errBuff*. If this parameter is 0, TimesTen does not return error messages to the calling application.
errLen	unsigned int*	A pointer to an unsigned integer where the actual length of the error message is returned. If it is NULL, TimesTen ignores this parameter.

Return codes

This utility returns the following codes as defined in `ttutillib.h`.

Code	Description
TTUTIL_SUCCESS	Returned upon success.
TTUTIL_INVALID_HANDLE	Returned if an invalid utility library handle is specified.
TTUTIL_NODATA	Returned if no error or warming information is retrieved.

Example

This example retrieves all error or warning information after calling
ttDestroyDataStore for the DSN named payroll.

```
char           errBuff[256];
int            rc;
unsigned int   retCode;
ttUtilErrType  retType;
ttUtilHandle   utilHandle;

rc = ttDestroyDataStore (utilHandle, "DSN=PAYROLL", 30);
if ((rc == TTUTIL_SUCCESS)
  printf ("Datastore payroll successfully destroyed.\n");
else if (rc == TTUTIL_INVALID_HANDLE)
  printf ("TimesTen utility library handle is invalid.\n");
else
    while ((rc = ttUtilGetError (utilHandle, 0,
        &retCode, &retType, errBuff, sizeof (errBuff),
        NULL)) != TTUTIL_NODATA)
    {
...
...
}
```

Notes

Each of the TimesTen C functions can potentially generate multiple errors and
warnings for a single call from an application. To retrieve all of these errors and
warnings, the application must make repeated calls to ttUtilGetError until it returns
TTUTIL_NODATA.

See also

ttUtilAllocEnv
ttUtilFreeEnv
ttUtilGetErrorCount

ttUtilGetErrorCount

Description

Retrieves the number of errors and warnings generated by the last call to the TimesTen C utility library functions, excluding ttUtilAllocEnv and ttUtilFreeEnv. Each of these functions can potentially generate multiple errors and warnings for a single call from an application. To retrieve all of these errors and warnings, the application must make repeated calls to ttUtilGetError until it returns TTUTIL_NODATA.

Required privilege

None

Syntax

```
ttUtilGetErrorCount (ttUtilHandle handle,
                     unsigned int* errCount)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
errCount	unsigned int*	Indicates the number of errors and warnings generated by the last call, excluding ttUtilAllocEnv and ttUtilFreeEnv, to the TimesTen utility library.

Return codes

The utility returns the following codes as defined in ttutillib.h.

Code	Description
TTUTIL_SUCCESS	Returned upon success.
TTUTIL_INVALID_HANDLE	Returned if an invalid utility library handle is specified.

Example

This example retrieves the error and warning count information after calling ttDestroyDataStore for the DSN named payroll.

```
int          rc;
unsigned int errCount;
ttUtilHandle utilHandle;

rc = ttDestroyDataStore (utilHandle, "DSN=payroll", 30);
if (rc == TTUTIL_SUCCESS)
  printf ("Datastore payroll successfully destroyed.\n")

else if (rc == TTUTIL_INVALID_HANDLE)
  printf ("TimesTen utility library handle is invalid.\n");
else
```

```
{
rc = ttUtilGetErrorCount(utilHandle, &errCount);
  ...
  ...
}
```

Notes

Each of the TimesTen utility library functions can potentially generate multiple errors and warnings for a single call from an application. To retrieve all of these errors and warnings, the application must make repeated calls to `ttUtilGetError` until it returns `TTUTIL_NODATA`.

ttUtilAllocEnv
ttUtilFreeEnv
ttUtilGetError

ttXactIdRollback

Description

Rolls back the transaction indicated by the transaction ID that is specified. The intended user of `ttXactIdRollback` is the `ttXactAdmin` utility. However, programs that want to have a thread with the power to roll back the work of other threads must ensure that those threads call the `ttXactIdGet` built-in procedure before beginning work and put the results into a location known to the thread that wishes to roll back the transaction. (Refer to "ttXactIdGet" in *Oracle TimesTen In-Memory Database Reference*.)

Required privilege

ADMIN

Syntax

```
ttXactIdRollback (ttUtilHandle handle, const char* connStr,
                  const char* xactId)
```

Parameters

Parameter	Type	Description
handle	ttUtilHandle	Specifies the TimesTen utility library environment handle allocated using ttUtilAllocEnv.
connStr	const char**	Specifies the connection string of the database, which contains the transaction to be rolled back.
xactId	const char*	Indicates the transaction ID for the transaction to be rolled back.

Example

This example rolls back a transaction with the ID 3.4567 in the database named `payroll`.

```
char            errBuff [256];
int             rc;
unsigned int    retCode;
ttUtilErrType   retType;
ttUtilHandle    utilHandle;
...
rc = ttXactIdRollback (utilHandle, "DSN=payroll", "3.4567");
if (rc == TTUTIL_SUCCESS)
  printf ("Transaction ID successfully rolled back.\n");
else if (rc == TTUTIL_INVALID_HANDLE)
  printf ("TimesTen utility library handle is invalid.\n");
else
  while ((rc = ttUtilGetError (utilHandle, 0, &retCode,
  &retType, errBuff, sizeof (errBuff), NULL)) != TTUTIL_NODATA)
   {
   ...
}
```

XLA Reference

This chapter provides reference information for the Transaction Log API (XLA) described in Chapter 5, "XLA and TimesTen Event Management". It includes the following topics:

- About XLA functions
- Summary of XLA functions by category
- XLA function reference
- XLA replication function reference
- C data structures used by XLA

About XLA functions

This section provides general information about XLA functions.

About return codes

All of the XLA API functions described in this chapter return a value of type `SQLRETURN`, which is defined by ODBC to have one of the following values:

- `SQL_SUCCESS`
- `SQL_SUCCESS_WITH_INFO`
- `SQL_NO_DATA_FOUND`
- `SQL_ERROR`

See "Handling XLA errors" on page 5-28 for information on handling XLA errors.

About parameter types (input, output, input/output)

In the function descriptions:

- All parameters are input-only unless otherwise indicated.
- Output parameters are prefixed with `OUT`.
- Input/output parameters are prefixed with `IN OUT`.

About results output by functions

Most routines in this API copy results to application buffers. Those few routines that produce pointers to buffers containing results are guaranteed as valid only until the next call with the same XLA handle.

Exceptions to this rule include the following.

- Buffers remain valid across calls to the `ttXlaError` function that supplies diagnostic information.

- Results returned by `ttXlaNextUpdate` remain valid until the next call to `ttXlaNextUpdate`.

- For `ttXlaAcknowledge`, if the application must retain access to the buffers for a longer time, it must copy the information from the buffer returned by XLA to an application-owned buffer.

Character string values in XLA are null-terminated, except for actual column values. Fixed-length `CHAR` columns are space-padded to their full length. `VARCHAR` columns have an explicit length encoded.

XLA uses the same data structures for both 32- and 64-bit platforms. The types `SQLUINTEGER` and `SQLUBIGINT` are used to refer to 32- and 64-bit integers unambiguously. Issues of alignment and padding are addressed by filling the type definition so that each `SQLUINTEGER` value is on a four-byte boundary and each `SQLUBIGINT` value is on an eight-byte boundary. For a description of storage requirements for other TimesTen data types, see "Understanding rows" in *Oracle TimesTen In-Memory Database Operations Guide*.

About required privileges

"Access control impact on XLA" on page 5-8 introduces the effects of TimesTen access control features on XLA functionality. Any XLA functionality requires the system privilege `XLA`.

Summary of XLA functions by category

As described in Chapter 5, "XLA and TimesTen Event Management", TimesTen XLA can be used to detect updates on a database or as a toolkit to build your own replication solution.

This section categorizes the XLA functions based on their use and provides a brief description of each function. It includes the following categories:

- XLA core functions
- XLA data type conversion functions
- XLA replication functions

XLA core functions

The following table lists all the XLA functions used in typical XLA operations, aside from data conversion functions which are listed separately below.

Function	Description
ttXlaAcknowledge	Acknowledges receipt of one or more transaction update records from the transaction log.
ttXlaClose	Closes the XLA handle opened by ttXlaPersistOpen.
ttXlaConvertCharType	Converts column data into the connection character set.
ttXlaDeleteBookmark	Deletes a transaction log bookmark.
ttXlaError	Retrieves error information.

Function	Description
ttXlaErrorRestart	Resets error stack information.
ttXlaGetColumnInfo	Retrieves information about all the columns in the table.
ttXlaGetLSN	Retrieves the log record identifier of the current bookmark for a database.
ttXlaGetTableInfo	Retrieves information about a table.
ttXlaGetVersion	Retrieves the current version of XLA.
ttXlaNextUpdate	Retrieves a batch of updates from TimesTen.
ttXlaNextUpdateWait	Retrieves a batch of updates from TimesTen. Will wait for a specified time if no updates are available in the transaction log.
ttXlaPersistOpen	Initializes a handle to a database to access the transaction log.
ttXlaSetLSN	Sets the log record identifier of the current bookmark for a database.
ttXlaSetVersion	Sets the XLA version to be used.
ttXlaTableByName	Finds the system and user table identifiers for a table given the table owner and name.
ttXlaTableStatus	Sets and retrieves XLA status for a table.
ttXlaTableVersionVerify	Checks whether the cached table definitions are compatible with the XLA record being processed.
ttXlaVersionColumnInfo	Retrieves information about the columns in a table for which a change update record must be processed.
ttXlaVersionCompare	Compares two XLA versions.

See "Writing an XLA event-handler application" on page 5-9 for a discussion on how to use most of these functions.

XLA data type conversion functions

The following table lists data type conversion functions.

Function	Description
ttXlaDateToODBCCType	Converts a TTXLA_DATE_TT value to an ODBC C value usable by applications.
ttXlaDecimalToCString	Converts a TTXLA_DECIMAL_TT value to a character string usable by applications.
ttXlaNumberToBigInt	Converts a TTXLA_NUMBER value to a SQLBIGINT C value usable by applications.
ttXlaNumberToCString	Converts a TTXLA_NUMBER value to a character string usable by applications.
ttXlaNumberToDouble	Converts a TTXLA_NUMBER value to a long floating point number value usable by applications.
ttXlaNumberToInt	Converts a TTXLA_NUMBER value to an integer usable by applications.
ttXlaNumberToSmallInt	Converts a TTXLA_NUMBER value to a SQLSMALLINT C value usable by applications.

Function	Description
ttXlaNumberToTinyInt	Converts a TTXLA_NUMBER value to a SQLCHAR C value usable by applications.
ttXlaNumberToUInt	Converts a TTXLA_NUMBER value to an unsigned integer usable by applications.
ttXlaOraDateToODBCTimeStamp	Converts a TTXLA_DATE value to an ODBC timestamp usable by applications.
ttXlaOraTimeStampToODBCTimeStamp	Converts a TTXLA_TIMESTAMP value to an ODBC timestamp usable by applications.
ttXlaRowidToCString	Converts a ROWID value to a character string value usable by applications.
ttXlaTimeToODBCCType	Converts a TTXLA_TIME value to an ODBC C value usable by applications.
ttXlaTimeStampToODBCCType	Converts a TTXLA_TIMESTAMP_TT value to an ODBC C value usable by applications.

For more information about XLA data types, see "About XLA data types" on page 5-7.

XLA replication functions

TimesTen replication as described in *Oracle TimesTen In-Memory Database Replication Guide* is sufficient for most customer needs; however, it is also possible to use XLA functions to replicate updates from one database to another. Implementing your own replication scheme on top of XLA in this way is fairly complicated, but can be considered if TimesTen replication is not feasible for some reason.

The following table lists functions used exclusively for XLA as a replication mechanism. (Reference information for these functions is in a separate section from other XLA functions, "XLA replication function reference" on page 9-52.)

Function	Description
ttXlaApply	Applies the update to the database associated with the XLA handle.
ttXlaCommit	Commits a transaction.
ttXlaGenerateSQL	Generates a SQL statement that expresses the effect of an update record.
ttXlaLookup	Looks for an update record for a table with a specific key value.
ttXlaRollback	Rolls back a transaction.
ttXlaTableCheck	Verifies that the named table in the table description received from the sending database is compatible with the receiving database.

See "Using XLA as a replication mechanism" on page 5-34 for a discussion on how to use these functions.

XLA function reference

This section provides reference information for XLA core functions and XLA data type conversion functions. The functions are listed in alphabetical order.

> **Note:**   Functions used exclusively for XLA as a replication mechanism are documented in a separate section, "XLA replication function reference" on page 9-52.

ttXlaAcknowledge

Description

This function is used to acknowledge that one or more records have been read from the transaction log by the `ttXlaNextUpdate` or `ttXlaNextUpdateWait` function.

After you make this call, the bookmark is reset so that you cannot reread any of the previously returned records. Call `ttXlaAcknowledge` only when messages have been completely processed.

Notes:

- The bookmark is only reset for the specified handle. Other handles in the system may still be able to access those earlier transactions.

- The bookmark is reset even if there are no relevant update records to acknowledge.

Note that `ttXlaAcknowledge` is an expensive operation that should be used only as necessary. Calling `ttXlaAcknowledge` more than once per reading of the transaction log file does not reduce the volume of the transaction log since XLA only purges transaction logs a file at a time. To detect when a new transaction log file is generated, you can find out which log file a bookmark is in by examining the `purgeLSN` (represented by the `PURGELSNHIGH` and `PURGELSNLOW` values) for the bookmark in the system table `SYS.TRANSACTION_LOG_API`. You can then call `ttXlaAcknowledge` to purge the old transaction log files. (Note that you must have `ADMIN` or `SELECT ANY TABLE` privilege to view this table.)

The second purpose of `ttXlaAcknowledge` is to ensure that the XLA application does not see the acknowledged records if it were to connect to a previously used bookmark by calling the `ttXlaPersistOpen` function with the `XLAREUSE` option. If you intend to reuse a bookmark, call `ttXlaAcknowledge` to reset the bookmark position to the current record before calling `ttXlaClose`.

See "Retrieving update records from the transaction log" on page 5-13 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaAcknowledge(ttXlaHandle_h handle)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

Example

```
rc = ttXlaAcknowledge(xlahandle);
```

See also

ttXlaNextUpdate
ttXlaNextUpdateWait

ttXlaClose

Description

Closes an XLA handle that was opened by `ttXlaPersistOpen`. See "Terminating an XLA application" on page 5-32 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaClose(ttXlaHandle_h handle)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	ODBC handle for the database

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

To close the XLA handle opened in the previous example, use the following call:

```
rc = ttXlaClose(xlahandle);
```

See also

ttXlaPersistOpen

ttXlaConvertCharType

Description

Converts the column data indicated by the *colinfo* and *tup* parameters into the connection character set associated with the transaction log handle and places the result in a buffer.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaConvertCharType (ttXlaHandle_h handle,
                                ttXlaColDesc_t* colinfo,
                                void* tup,
                                void* buf,
                                size_t buflen)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
colinfo	ttXlaColDesc_t*	Pointer to the buffer that holds the column descriptions
tup	void*	Data to be converted
buf	void*	Location where the converted data is placed
buflen	size_t	Size of the buffer where the converted data is placed

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaDateToODBCCType

Description

Converts a TTXLA_DATE_TT value to an ODBC C value usable by applications. See "Converting complex data types" on page 5-23 for a discussion about using this function.

Call this function only on a column of data type TTXLA_DATE_TT. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaDateToODBCCType(void* fromData,
                                 out DATE_STRUCT* returnData)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the date value returned from the transaction log
returnData	DATE_STRUCT*	Pointer to storage allocated to hold the converted date

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaDecimalToCString

Description

Converts a `TTXLA_DECIMAL_TT` value to a string usable by applications. The scale and precision values can be obtained from the `ttXlaColDesc_t` structure returned by the `ttXlaGetColumnInfo` function. The *scale* parameter specifies the maximum number of digits after the decimal point. If the decimal value is larger than 1, the *precision* parameter should specify the maximum number of digits before and after the decimal point. If the decimal value is less than 1, *precision* equals *scale*.

Call this function only for a column of type `TTXLA_DECIMAL_TT`. The data type can be obtained from the `ttXlaColDesc_t` structure returned by the `ttXlaGetColumnInfo` function.

See "Converting complex data types" on page 5-23 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaDecimalToCString(void* fromData,
                                out char* returnData,
                                SQLSMALLINT precision,
                                SQLSMALLINT scale)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the decimal value returned from the transaction log
returnData	char*	Pointer to storage allocated to hold the converted string
precision	SQLSMALLINT	If *fromData* is greater than 1, the maximum number of digits before and after the decimal point
		If *fromData* is less than 1, same as scale
scale	SQLSMALLINT	Maximum number of digits after the decimal point

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

Example

This example assumes you have obtained the *offset*, *precision*, and *scale* values from a `ttXlaColDesc_t` structure and used the offset to obtain a decimal value, *pColVal*, in a row returned in a transaction log record.

```
char decimalData[50];
static ttXlaColDesc_t colDesc[255];
```

```
        rc = ttXlaDecimalToCString(pColVal, (char*)&decimalData,
                                   colDesc->precision,
                                   colDesc->scale);
```

ttXlaDeleteBookmark

Description

Deletes the bookmark associated with the specified transaction log handle. After the bookmark has been deleted, it is no longer accessible and its identifier may be reused for another bookmark. The deleted bookmark is no longer associated with the database handle and the effect is the same as having opened the connection with the XLANONE option.

If the bookmark is in use, it cannot be deleted until it is no longer in use.

See "Deleting bookmarks" on page 5-31 for a discussion about using this function.

> **Notes:**
> - Do not confuse this with the TimesTen built-in procedure ttXlaBookmarkDelete, documented in "ttXlaBookmarkDelete" in *Oracle TimesTen In-Memory Database Reference.*
> - You cannot delete replicated bookmarks while the replication agent is running.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaDeleteBookmark(ttXlaHandle_h handle)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

Delete the bookmark for xlahandle:

```
rc = ttXlaDeleteBookmark(xlahandle);
```

See also

ttXlaPersistOpen
ttXlaGetLSN
ttXlaSetLSN

ttXlaError

Description

Reports details of any errors encountered from the previous call on the given transaction log handle. Multiple errors may be returned through subsequent calls to ttXlaError. The error stack is cleared following each call to a function other than ttXlaError itself and ttXlaErrorRestart.

See "Handling XLA errors" on page 5-28 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaError(ttXlaHandle_h handle,
                     out SQLINTEGER* errCode,
                     out char* errMessage,
                     SQLINTEGER maxLen,
                     out SQLINTEGER* retLen)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
errCode	SQLINTEGER*	Code of the error message to be copied into the errMessage buffer
errMessage	char*	Buffer to hold the error text
maxLen	SQLINTEGER	Maximum length of the errMessage buffer
retLen	SQLINTEGER*	Actual size of the error message

Returns

Returns SQL_SUCCESS if error information is returned, or SQL_NO_DATA_FOUND if no more errors are found in the error stack. If the errMessage buffer is not large enough, ttXlaError returns SQL_SUCCESS_WITH_INFO.

Example

There can be multiple errors on the error stack. This example shows how to read them all.

```
char message[100];
SQLINTEGER code;

for (;;) {
  rc = ttXlaError(xlahandle, &code, message, sizeof (message), &retLen);
  if (rc == SQL_NO_DATA_FOUND)
      break;
  if (rc == SQL_ERROR) {
      printf("Error in fetching error message\n");
      break;
  }
  else {
```

```
        printf("Error code %d: %s\n", code, message);
  }
}
```

Note

If you use multiple threads to access a TimesTen transaction log over a single XLA connection, TimesTen creates a latch to control concurrent access. If for some reason the latch cannot be acquired by a thread, the XLA function returns `SQL_INVALID_HANDLE`.

See also

ttXlaErrorRestart

ttXlaErrorRestart

Description

Resets the error stack so that an application can reread the errors. See "Handling XLA errors" on page 5-28 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaErrorRestart(ttXlaHandle_h handle)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

```
rc = ttXlaErrorRestart(xlahandle);
```

See also

ttXlaError

ttXlaGetColumnInfo

Description

Retrieves information about all the columns in the table. Normally, the output parameter for number of columns returned, *nreturned*, is set to the number of columns returned in *colinfo*. The *systemTableID* or *userTableID* parameter describes the desired table. This call is serialized with respect to changes in the table definition.

See "Obtaining column descriptions" on page 5-18 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaGetColumnInfo(ttXlaHandle_h handle,
                             SQLUBIGINT systemTableID,
                             SQLUBIGINT userTableID,
                             out ttXlaColDesc_t* colinfo,
                             SQLINTEGER maxcols,
                             out SQLINTEGER* nreturned)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
systemTableID	SQLUBIGINT	System ID of table
userTableID	SQLUBIGINT	User ID of table
colinfo	ttXlaColDesc_t*	Pointer to the buffer large enough to hold a separate description for *maxcols* columns
maxcols	SQLINTEGER	Maximum number of columns that can be stored in the *colInfo* buffer If the table contains more than *maxcols* columns, an error is returned.
nreturned	SQLINTEGER*	Number of columns returned

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

For this example, assume the following definitions:

```
ttXlaColDesc_t colinfo[20];
SQLUBIGINT systemTableID, userTableID;
SQLINTEGER ncols;
```

To get the description of up to 20 columns using the system table identifier, issue the following call:

```
rc = ttXlaGetColumnInfo(xlahandle, systemTableID, 0, colinfo, 20, &ncols);
```

Likewise, the user table identifier can be used:

```
rc = ttXlaGetColumnInfo(xlahandle, 0, userTableID, colinfo, 20, &ncols);
```

See "ttXlaColDesc_t" on page 9-76 for details and an example on how to access the column data in a returned row.

ttXlaTimeToODBCCType
ttXlaTimeStampToODBCCType

ttXlaGetLSN

Description

Returns the Current Read log record identifier for the connection specified by the transaction log handle. See "How bookmarks work" on page 5-4 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaGetLSN(ttXlaHandle_h handle,
                        out tt_XlaLsn_t* LSN)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
LSN	tt_XlaLsn_t*	Current Read log record identifier for the handle

---

Note: Be aware that tt_XlaLsn_t, particularly the *logFile* and *logOffset* fields, is used differently than in earlier releases, referring to log record identifiers rather than sequentially increasing LSNs. See the note in "tt_XlaLsn_t" on page 9-80.

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

This example returns the Current Read log record identifier, CurLSN.

```
tt_XlaLsn_t CurLSN;

rc = ttXlaGetLSN(xlahandle, &CurLSN);
```

See also

ttXlaSetLSN

ttXlaGetTableInfo

Description

Retrieves information about the rows in the table (refer to the description of the ttXlaTblDesc_t data type.) If the *userTableID* parameter is nonzero, then it is used to locate the desired table. Otherwise, the *systemTableID* value is used to locate the table. If both are zero, an error is returned. The description is stored in the output parameter *tblinfo*. This call is serialized with respect to changes in the table definition.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaGetTableInfo(ttXlaHandle_h handle,
                            SQLUBIGINT systemTableID,
                            SQLUBIGINT userTableID,
                            out ttXlaTblDesc_t* tblinfo)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
systemTableID	SQLUBIGINT	System table ID
userTableID	SQLUBIGINT	User table ID
tblinfo	ttXlaTblDesc_t*	Row information

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

For this example, assume the following definitions:

```
ttXlaTblDesc_t tabinfo;
SQLUBIGINT systemTableID, userTableID;
```

To get table information using a system identifier, find the system table identifier using ttXlaTableByName or other means and issue the following call:

```
rc = ttXlaGetTableInfo(xlahandle, systemTableID, 0, &tabinfo);
```

Alternatively, the table information can be retrieved using a user table identifier:

```
rc = ttXlaGetTableInfo(xlahandle, 0, userTableID, &tabinfo);
```

See also

ttXlaGetColumnInfo

ttXlaGetVersion

Description

This function is used in combination with ttXlaSetVersion to ensure XLA applications written for older versions of XLA operate on a new version. The configured version is typically the older version, while the actual version is the newer one.

The function retrieves the currently configured XLA version and stores it into *configuredVersion* parameter. The actual version of the underlying XLA is stored in *actualVersion*. Due to calls on ttXlaSetVersion, the results in *configuredVersion* may vary from one call to the next, but the results in *actualVersion* remain the same.

See "XLA basics" on page 5-2 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaGetVersion(ttXlaHandle_h handle,
                          out ttXlaVersion_t* configuredVersion,
                          out ttXlaVersion_t* actualVersion)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
configuredVersion	ttXlaVersion_t*	Configured version of XLA
actualVersion	ttXlaVersion_t*	Actual version of XLA

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

Assume the following directions for this example:

```
ttXlaVersion_t configured, actual;
```

To determine the current version configuration, use the following call:

```
rc = ttXlaGetVersion(xlahandle, &configured, &actual);
```

See also

ttXlaVersionCompare
ttXlaSetVersion

ttXlaNextUpdate

Description

This function fetches up to a specified maximum number of update records from the transaction log and returns the records associated with committed transactions to a specified buffer. The actual number of returned records is reported in the *nreturned* output parameter. This function requires a bookmark to be present in the database and to be associated with the connection used by the function.

Each call to ttXlaNextUpdate resets the bookmark to the last record read to enable the next call to ttXlaNextUpdate to return the next list of records.

See "Retrieving update records from the transaction log" on page 5-13 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNextUpdate(ttXlaHandle_h handle,
                          out ttXlaUpdateDesc_t*** records,
                          SQLINTEGER maxrecords,
                          out SQLINTEGER* nreturned)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
records	ttXlaUpdateDesc_t***	Buffer to hold the completed transaction records
maxrecords	SQLINTEGER	Maximum number of records to be fetched
nreturned	SQLINTEGER*	Actual number of returned records, where 0 is returned if no update data is available

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

This example retrieves up to 100 records and describes a loop in which each record can be processed:

```
ttXlaUpdateDesc_t** records;
SQLINTEGER nreturned;
SQLINTEGER i;

rc = ttXlaNextUpdate(xlahandle, &records, 100, &nreturned);
/* Check for errors; if none, process the records */
for (i = 0; i < nreturned; i++) {
  process(records[i]);
}
```

Notes

Updates are generated for all data definition statements, regardless of tracking status. Updates are generated for data update operations for all tracked tables associated with the bookmark.

In addition, updates are generated for certain special operations, including assigning application-level identifiers for tables and columns and changing a table's tracking status.

See also

ttXlaNextUpdateWait
ttXlaAcknowledge

ttXlaNextUpdateWait

Description

This is similar to the `ttXlaNextUpdate` function, with the addition of a *seconds* parameter that specifies the number of seconds to wait if no records are available in the transaction log. The actual number of seconds of wait time can be up to two seconds more than the specified *seconds* value.

Also see

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNextUpdateWait(ttXlaHandle_h handle,
                              out ttXlaUpdateDesc_t*** records,
                              SQLINTEGER maxrecords,
                              out SQLINTEGER* nreturned,
                              SQLINTEGER seconds)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
records	ttXlaUpdateDesc_t***	Buffer to hold the completed transaction records
maxrecords	SQLINTEGER	Maximum number of records to be fetched **Note**: The largest effective value is 1000 records.
nreturned	SQLINTEGER*	Actual number of records returned, where 0 is returned if no update data is available within the seconds wait period
seconds	SQLINTEGER	Number of seconds to wait if the log is empty

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

Example

This example retrieves up to 100 records and will wait for up to 60 seconds if there are no records available in the transaction log.

```
ttXlaUpdateDesc_t** records;
SQLINTEGER nreturned;
SQLINTEGER i;

rc = ttXlaNextUpdateWait(xlahandle, &records, 100, &nreturned, 60);
/* Check for errors; if none, process the records */
for (i = 0; i < nreturned; i++) {
  process(records[i]);
}
```

See also

ttXlaNextUpdate
ttXlaAcknowledge

ttXlaNumberToBigInt

Description

Converts a TTXLA_NUMBER value to a SQLBIGINT value usable by an application.

Call this function only for a column of type TTXLA_NUMBER. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNumberToBigInt(void* fromData,
                              SQLBIGINT* bint)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
bint	SQLBIGINT*	The SQLBIGINT value converted from the XLA number value

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaNumberToCString

Description

Converts a `TTXLA_NUMBER` value to a character string usable by an application.

Call this function only for a column of type `TTXLA_NUMBER`. The data type can be obtained from the `ttXlaColDesc_t` structure returned by the `ttXlaGetColumnInfo` function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNumberToCString(ttXlaHandle_h handle,
                               void* fromData,
                               char* buf,
                               int buflen
                               int* reslen)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
buf	char*	Location where the converted data is placed
buflen	int	Size of the buffer where the converted data is placed
reslen	int*	Number of bytes that were written, assuming *buflen* is large enough (otherwise, the number of bytes that would have been written)

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

ttXlaNumberToDouble

Description

Converts a TTXLA_NUMBER value to a long floating point number value usable by applications.

Call this function only for a column of type TTXLA_NUMBER. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNumberToDouble(void* fromData,
                              double* dbl)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
dbl	double*	The long floating point number value converted from the XLA number value

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaNumberToInt

Description

Converts a TTXLA_NUMBER value to a SQLINTEGER value usable by an application.

Call this function only for a column of type TTXLA_NUMBER. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNumberToInt(void* fromData,
                           SQLINTEGER* ival)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
ival	SQLINTEGER*	The SQLINTEGER value converted from the XLA number value

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaNumberToSmallInt

Description

Converts a TTXLA_NUMBER value to a SQLSMALLINT value usable by an application.

Call this function only for a column of type TTXLA_NUMBER. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNumberToSmallInt(void* fromData,
                                SQLSMALLINT* smint)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
smint	SQLSMALLINT*	The SQLSMALLINT value converted from the XLA number value

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaNumberToTinyInt

Description

Converts a TTXLA_NUMBER value to a tiny integer value usable by an application.

Call this function only for a column of type TTXLA_NUMBER. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNumberToTinyInt(void* fromData,
                               SQLCHAR* tiny)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
tiny	SQLCHAR*	The tiny integer value converted from the XLA number value

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaNumberToUInt

Description

Converts a TTXLA_NUMBER value to an unsigned integer value usable by an application.

Call this function only for a column of type TTXLA_NUMBER. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaNumberToInt(void* fromData,
                           SQLUINTEGER* ival)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
ival	SQLUINTEGER*	The integer value converted from the XLA number value

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaOraDateToODBCTimeStamp

Description

Converts a TTXLA_DATE value to an ODBC timestamp.

Call this function only for a column of type TTXLA_DATE. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaOraDateToODBCTimeStamp(void* fromData,
                                      TIMESTAMP_STRUCT* returnData)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
returnData	TIMESTAMP_STRUCT*	ODBC timestamp value converted from the XLA Oracle DATE value

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

ttXlaOraTimeStampToODBCTimeStamp

Description

Converts a `TTXLA_TIMESTAMP` value to an ODBC timestamp.

Call this function only for a column of type `TTXLA_TIMESTAMP`. The data type can be obtained from the `ttXlaColDesc_t` structure returned by the `ttXlaGetColumnInfo` function.

Syntax

```
SQLRETURN ttXlaOraTimeStampToODBCTimeStamp(void* fromData,
                                           TIMESTAMP_STRUCT* returnData)
```

Required privilege

XLA

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the number value returned from the transaction log
returnData	TIMESTAMP_STRUCT*	ODBC timestamp value converted from the XLA Oracle TIMESTAMP value

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

ttXlaPersistOpen

Description

Initializes a transaction log handle to a database to enable access to the transaction log. The *hdbc* parameter is an ODBC connection handle to a database. Create only one XLA handle for each ODBC connection. After you have created an XLA handle on an ODBC connection, do not issue any other ODBC calls over the ODBC connection until it is closed by ttXlaClose.

The *tag* is a string that identifies the XLA bookmark (see "About XLA bookmarks" on page 5-4). The *tag* can identify a new bookmark, either non-replicated or replicated, or one that exists in the system, as specified by the *options* parameter. The *handle* parameter is initialized by this call and must be provided on each subsequent call to XLA.

Some actions can be done without a bookmark. When performing these types of actions, you can use the XLANONE option to access the transaction log without a bookmark. Actions that *cannot* be done without a bookmark are the following:

- ttXlaAcknowledge

- ttXlaGetLSN

- ttXlaSetLSN

- ttXlaNextUpdate

- ttXlaNextUpdateWait

Multiple applications can concurrently read from the transaction log. See "Initializing XLA and obtaining an XLA handle" on page 5-11 for a discussion about using this function.

When this function is successful, XLA sets the autocommit mode to off.

If this function fails but still creates a handle, the handle must be closed to prevent memory leaks.

> **Note:** Space is allocated by this call. Call ttXlaClose to free space when you are done.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaPersistOpen(SQLHDBC hdbc,
                           SQLCHAR* tag,
                           SQLUINTEGER options,
                           out ttXlaHandle_h* handle)
```

Parameters

Parameter	Type	Description
hdbc	SQLHDBC	ODBC handle for the database

Parameter	Type	Description
tag	SQLCHAR*	Identifier for the XLA bookmark
		This can be null, in which case *options* should be set to XLANONE. Maximum allowed length is 31.
options	SQLUINTEGER	Bookmark options:
		■ XLANONE: Connect without a bookmark. The *tag* field is ignored.
		■ XLACREAT: Create a new non-replicated bookmark. Fails if a bookmark already exists.
		■ XLAREPL: Create a new replicated bookmark. Fails if a bookmark already exists.
		■ XLAREUSE: Associate with an existing bookmark (non-replicated or replicated). Fails if the bookmark does not exist.
handle	ttXlaHandle_h*	Transaction log handle returned by this call

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

This example opens a transaction log, returns a handle named xlahandle, and creates a new non-replicated bookmark named mybookmark:

```
SQLHDBC hdbc;
ttXlaHandle_h xlahandle;

rc = ttXlaPersistOpen(hdbc, ( SQLCHAR*)mybookmark,
                      XLACREAT, &xlahandle);
```

Alternatively, create a new replicated bookmark as follows:

```
SQLHDBC hdbc;
ttXlaHandle_h xlahandle;

rc = ttXlaPersistOpen(hdbc, ( SQLCHAR*)mybookmark,
                      XLAREPL, &xlahandle);
```

Note

Multithreaded applications should create a separate XLA handle for each thread. If multiple threads must use the same XLA handle, use a mutex to serialize thread access to that XLA handle so that only one thread can execute an XLA operation at a time.

ttXlaClose
ttXlaDeleteBookmark
ttXlaGetLSN
ttXlaSetLSN

ttXlaRowidToCString

Description

Converts a ROWID value to a string value usable by applications.

Required privilege

XLA

Syntax

SQLRETURN ttXlaRowidToCString(void* *fromData*, char* *buf*, int *buflen*)

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the ROWID value returned from the transaction log
buf	char*	Pointer to storage allocated to hold the converted string
buflen	int	Length of the converted string

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

```
char charbuf[18];
void* rowiddata;
/* ... */
rc = ttXlaRowidToCString(rowiddata, charbuf, sizeof(charbuf));
```

ttXlaSetLSN

Description

Sets the Current Read log record identifier for the database specified by the transaction handle. The specified *LSN* value should be returned from ttXlaGetLSN. It cannot be a user-created value and cannot be earlier than the current bookmark Initial Read log record identifier.

See "About XLA bookmarks" on page 5-4 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaSetLSN(ttXlaHandle_h handle,
                      tt_XlaLsn_t* LSN)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
LSN	tt_XlaLsn_t*	New log record identifier for the handle

> **Note:** Be aware that tt_XlaLsn_t, particularly the *logFile* and *logOffset* fields, is used differently than in earlier releases, referring to log record identifiers rather than sequentially increasing LSNs. See the note in "tt_XlaLsn_t" on page 9-80.

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

This example sets the Current Read log record identifier to CurLSN.

```
tt_XlaLsn_t CurLSN;

rc = ttXlaSetLSN(xlahandle, &CurLSN);
```

See also

ttXlaGetLSN

ttXlaSetVersion

Description

Sets the version of XLA to be used by the application. This version must be either the same as the version received from ttXlaGetVersion or from an earlier version.

See "XLA basics" on page 5-2 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaSetVersion(ttXlaHandle_h handle,
                          ttXlaVersion_t* version)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
version	ttXlaVersion_t*	Desired version of XLA

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

To set the configured version to the value specified in requestedVersion, issue the following call:

```
rc = ttXlaSetVersion(xlahandle, &requestedVersion);
```

See also

ttXlaVersionCompare
ttXlaGetVersion

ttXlaTableByName

Description

Finds the system and user table identifiers for a table or materialized view by providing the owner and name of the table or view. See "Specifying which tables to monitor for updates" on page 5-11 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaTableByName(ttXlaHandle_h handle,
                           char* owner,
                           char* name,
                           out SQLUBIGINT* sysTableID,
                           out SQLUBIGINT* userTableID)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
owner	char*	Owner for the table or view as a string
name	char*	Name of the table or view
sysTableID	SQLUBIGINT*	System table ID
userTableID	SQLUBIGINT*	User table ID

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

To get the system and user table IDs associated with the table PURCHASING.INVOICES, use the following call:

```
SQLUBIGINT sysTableID;
SQLUBIGINT userTableID;

rc = ttXlaTableByName(xlahandle, "PURCHASING", "INVOICES",
                      &sysTableID, &userTableID);
```

See also

ttXlaTableStatus

ttXlaTableStatus

Description

Returns the update status for a table. Identify the table by specifying either a user ID (*userTableID*) or a system ID (*systemTableID*). If *userTableID* is nonzero, it is used to locate the table. Otherwise *systemTableID* is used. If both are zero, an error is returned.

Specifying a value for *newstatus* sets the update status to **newstatus*. A nonzero status means the table specified by *systemTableID* is available through XLA. Zero means the table is not tracked. Changes to table update status are effective immediately.

Updates to a table are tracked only if update tracking was enabled for the table at the time the update was performed. This call is serialized with respect to updates to the underlying table. Therefore, transactions that update the table run either completely before or completely after the change to table status.

To use ttXlaTableStatus, the user must be connected to a bookmark. The function reports inserts, updates, and deletes only to the bookmark that has subscribed to the table. It reports DDL events to all bookmarks. DDL events include CREATAB, DROPTAB, CREAIND, DROPIND, CREATVIEW, DROPVIEW, CREATSEQ, DROPSEQ, CREATSYN, DROPSYN, ADDCOLS, DRPCOLS, TRUNCATE, SETTBL1, and SETCOL1 transactions. See "ttXlaUpdateDesc_t" on page 9-65 for information about these event types.

See "Specifying which tables to monitor for updates" on page 5-11 for a discussion about using this function.

> **Note:** DML updates to a table being tracked through XLA will not prevent ttXlaTableStatus from running. However, DDL updates to the table being tracked, which take a lock on SYS.TABLES, will delay ttXlaTableStatus from running in serializable isolation against SYS.TABLES.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaTableStatus(ttXlaHandle_h handle,
                           SQLUBIGINT systemTableID,
                           SQLUBIGINT userTableID,
                           out SQLINTEGER* oldstatus,
                           SQLINTEGER* newstatus)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
systemTableID	SQLUBIGINT	System ID of table
userTableID	SQLUBIGINT	User ID of table

Parameter	Type	Description
oldstatus	SQLINTEGER*	XLA old status:
		■ 1: On
		■ 0: Off
newstatus	SQLINTEGER*	XLA new status:
		■ 1: On
		■ 0: Off

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

The following examples assume that the system or user table identifiers are found using ttXlaTableByName or some other means.

Assume these declarations for the example:

```
SQLUBIGINT systemTableID;
SQLUBIGINT userTableID;
SQLINTEGER currentStatus, requestedStatus;
```

To find the status of a table given its system table identifier, use the following call:

```
/* Get system table identifier into systemTableID, then ... */
rc = ttXlaTableStatus(xlahandle, systemTableID, 0,
                      &currentStatus, NULL);
```

The *currentStatus* value will be nonzero if update tracking for the table is enabled, or zero otherwise.

To enable update tracking for a table given a system table identifier, set the requested status to 1 as follows:

```
requestedStatus = 1;

rc = ttXlaTableStatus(xlahandle, systemTableID, 0,
                      NULL, &requestedStatus);
```

You can set a new update tracking status and retrieve the current status in a single call, as in the following example:

```
requestedStatus = 1;

rc = ttXlaTableStatus(xlahandle, systemTableID, 0,
                      &currentStatus, &requestedStatus);
```

The above call enables update tracking for a table by system table identifier and retrieves the prior update tracking status in the variable *currentStatus*.

All of these examples can be done using user table identifiers as well. To retrieve the update tracking status of a table through its user table identifier, use the following call:

```
/* Get system table identifier into userTableID, then ... */

rc = ttXlaTableStatus(xlahandle, 0, userTableID,
                      &currentStatus, NULL);
```

See also

ttXlaTableByName

ttXlaTableVersionVerify

Description

Verifies that the cached table definitions are compatible with the XLA record being processed. Table definitions change only when the ALTER TABLE statement is used to add or remove columns.

You can monitor the XLA stream for XLA records of transaction type ADDCOLS and DRPCOLS to avoid the overhead of using this function. When an XLA record of transaction type ADDCOLS or DROPCOLS is encountered, refresh the table and column definitions. See "Inspecting record headers and locating row addresses" on page 5-15 for information about monitoring XLA records for transaction type.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaTableVersionVerify(ttXlaHandle_h handle
                                  ttXlaTblVerDesc_t* table,
                                  ttXlaUpdateDesc_t* record
                                  out SQLINTEGER* compat)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
table	ttXlaTblVerDesc_t*	A cached table description
record	ttXlaUpdateDesc_t*	XLA record to be processed
compat	SQLINTEGER*	Compatibility information: ■ 1: Tables are compatible. ■ 0: Tables are not compatible.

Returns

Returns SQL_SUCCESS if cached table definition is compatible with the XLA record being processed. Otherwise, use ttXlaError to report the error.

Example

This example checks the compatibility of a table.

```
SQLINTEGER compat;
ttXlaTbVerDesc_t table;
ttXlaUpdateDesc_t* record;
/*
 * Get the desired table definitions into the variable "table"
 */
rc = ttXlaTableVersionVerify(xlahandle, &table, record, &compat);
if (compat) {
/*
 * Compatible
 */
}
```

```
else {
/*
 * Not compatible or some other error occurred
 * If not compatible, issue a call to ttXlaVersionTableInfo and
 * ttXlaVersionColumnInfo to get the new definition.
 */
}
```

See also

ttXlaVersionColumnInfo
ttXlaVersionTableInfo

ttXlaTimeToODBCCType

Description

Converts a TTXLA_TIME value to an ODBC C value usable by applications. See "Converting complex data types" on page 5-23 for a discussion about using this function.

Call this function only for a column of type TTXLA_TIME. The data type can be obtained from the ttXlaColDesc_t structure returned by the ttXlaGetColumnInfo function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaTimeToODBCCType (void* fromData,
                                out TIME_STRUCT* returnData)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the time value returned from the transaction log
returnData	TIME_STRUCT*	Pointer to storage allocated to hold the converted time

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

This example assumes you have used the *offset* value returned in a ttXlaColDesc_t structure to obtain a time value, *pColVal*, from a row returned in a transaction log record.

```
TIME_STRUCT time;

rc = ttXlaTimeToODBCCType(pColVal, &time);
```

ttXlaTimeStampToODBCCType

Description

Converts a `TTXLA_TIMSTAMP_TT` value to an ODBC C value usable by applications. See "Converting complex data types" on page 5-23 for a discussion about using this function.

Call this function only for a column of type `TTXLA_TIMSTAMP_TT`. The data type can be obtained from the `ttXlaColDesc_t` structure returned by the `ttXlaGetColumnInfo` function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaTimeStampToODBCCType(void* fromData,
                                    out TIMESTAMP_STRUCT* returnData)
```

Parameters

Parameter	Type	Description
fromData	void*	Pointer to the timestamp value returned from the transaction log
returnData	TIMESTAMP_STRUCT*	Pointer to storage allocated to hold the converted timestamp

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

Example

This example assumes you have used the *offset* value returned in a `ttXlaColDesc_t` structure to obtain a timestamp value, *pColVal*, from a row returned in a transaction log record.

```
TIMESTAMP_STRUCT timestamp;

rc = ttXlaTimeStampToODBCCType(pColVal, &timestamp);
```

ttXlaVersionColumnInfo

Description

Retrieves information about the columns in a table for which a change update XLA record must be processed.

Required privilege

```
XLA
```

Syntax

```
SQLRETURN ttXlaVersionColumnInfo(ttXlaHandle_h handle,
                                 ttXlaUpdateDesc_t* record,
                                 out ttXlaColDesc_t* colinfo,
                                 SQLINTEGER maxcols,
                                 out SQLINTEGER* nreturned)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
record	ttXlaUpdateDesc_t*	XLA record to be processed
colinfo	ttXlaColDesc_t*	A pointer to the buffer large enough to hold a description for maxcols columns
maxcols	SQLINTEGER	Maximum number of columns the table can have **Note**: If the table contains more than maxcols columns, an error is returned.
nreturned	SQLINTEGER*	Number of columns returned

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

For this example, assume the following definitions:

```
ttXlaHandle_h xlahandle
ttXlaUpdateDesc_t* record;
ttXlaColDesc_t colinfo[20];
SQLINTEGER ncols;
```

The following call retrieves the description of up to 20 columns:

```
rc = ttXlaVersionColumnInfo(xlahandle, record, colinfo, 20, &ncols);
```

ttXlaVersionCompare

Description

Compares two XLA versions and returns the result.

Required privilege

```
XLA
```

Syntax

```
SQLRETURN ttXlaVersionCompare(ttXlaHandle_h handle,
                              ttXlaVersion_t* version1,
                              ttXlaVersion_t* version2,
                              out SQLINTEGER* comparison)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
version1	ttXlaVersion_t*	Version of XLA to compare with *version2*
version2	ttXlaVersion_t*	Version of XLA to compare with *version1*
comparison	SQLINTEGER*	Comparison result: ■ 0: Indicates *version1* and *version2* match. ■ -1: Indicates *version1* is earlier than *version2*. ■ +1: Indicates *version1* is later than *version2*.

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

To compare the configured version against the actual version of XLA, issue the following call:

```
ttXlaVersion_t configured, actual;
SQLINTEGER comparision;

rc = ttXlaGetVersion (xlahandle, &configured, &actual);
rc = ttXlaVersionCompare (xlahandle, &configured, &actual,
                          &comparison);
```

Notes

When connecting two systems with XLA-based replication, use the following protocol:

1. At the primary site, retrieve the XLA version using ttXlaGetVersion. Send this version information to the standby site.

2. At the standby site, retrieve the XLA version using ttXlaGetVersion. Use ttXlaVersionCompare to determine which version is earlier. The earlier version

number must be used to ensure proper operation between the two sites. Use `ttXlaSetVersion` to specify the version of the interface to use at the standby site. Send the earlier version number back to the primary site.

3. When the chosen version is received at the primary site, use `ttXlaSetVersion` to specify the version of XLA to use.

See also

ttXlaGetVersion
ttXlaSetVersion

ttXlaVersionTableInfo

Description

Retrieves the table definition for the change update record that must be processed. The table description is stored in the *tableinfo* output parameter.

Required privilege

```
XLA
```

Syntax

```
SQLRETURN ttXlaVersionTableInfo(ttXlaHandle_h handle,
                                ttXlaUpdateDesc_t* record,
                                out ttXlaTblVerDesc_t* tblinfo)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
record	ttXlaUpdateDesc_t*	XLA record to be processed
tableinfo	ttXlaTblVerDesc_t*	Information about table definition

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

For this example, assume the following definitions:

```
ttXlaHandle_h xlahandle;
ttXlaUpdateDesc_t* record;
ttXlaTblVerDesc_t tabinfo;
```

The following call retrieves a table definition:

```
rc = ttXlaVersionTableInfo(xlahandle, record, &tabinfo);
```

XLA replication function reference

TimesTen replication as described in *Oracle TimesTen In-Memory Database Replication Guide* is sufficient for most customer needs; however, it is also possible to use XLA functions to replicate updates from one database to another. Implementing your own replication scheme on top of XLA in this way is fairly complicated, but can be considered if TimesTen replication is not feasible for some reason.

This section documents the functions that are exclusive to using XLA as a replication mechanism. Functions are listed in alphabetical order.

ttXlaApply

This function is part of XLA replication functionality and is not appropriate for use in a typical XLA application.

Description

Applies an update to the database associated with the transaction log handle. The return value indicates whether the update was successful. The return also shows if the update encountered a persistent problem. (To see whether the update encountered a transient problem such as a deadlock or timeout, you must call ttXlaError and check the error code.)

If the ttXlaUpdateDesc_t record is a transaction commit, the underlying database transaction is committed. No other transaction commits are performed by ttXlaApply. If the parameter *test* is true, the "old values" in the update description are compared against the current contents of the database for record updates and deletions. If the old value in the update description does not match the corresponding row in the database, this function rejects the update and returns an sb_ErrXlaTupleMismatch error.

See "Using XLA as a replication mechanism" on page 5-34 for a discussion about using this function.

> **Note:** ttXlaApply cannot be used if the table definition was updated since it was originally written to the transaction log. Unique key and foreign key constraints are checked at the row level rather than at the statement level.

Required privilege

ADMIN

Additional privileges may be required on the target database for the ttXlaApply operation. For example, to apply a CREATETAB (create table) record to the target database, you must have CREATE TABLE or CREATE ANY TABLE privilege, as appropriate.

Syntax

```
SQLRETURN ttXlaApply(ttXlaHandle_h handle,
                     ttXlaUpdateDesc_t* record,
                     SQLINTEGER test)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
record	ttXlaUpdateDesc_t*	Transaction to generate SQL statement
test	SQLINTEGER	Test for old values: ■ 1: Test on ■ 0: Test off

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

If *test* is 1 and `ttXlaApply` detects an update conflict, an `sb_ErrXlaTupleMismatch` error is returned.

Example

This example applies an update to a database without testing for the previous value of the existing record:

```
ttXlaUpdateDesc_t record;
rc = ttXlaApply(xlahandle, &record, 0);
```

Note

When calling `ttXlaApply`, it is possible for the update to timeout or deadlock with concurrent transactions. In such cases, it is the application's responsibility to roll the transaction back and reapply the updates.

See also

ttXlaCommit
ttXlaRollback
ttXlaLookup
ttXlaTableCheck
ttXlaGenerateSQL

ttXlaCommit

This function is part of XLA replication functionality and is not appropriate for use in a typical XLA application.

Description

Commits the current transaction being applied on the transaction log handle. This routine commits the transaction regardless of whether the transaction has completed. You can call this routine to respond to transient errors (timeout or deadlock) reported by `ttXlaApply`, which applies the current transaction if it does not encounter an error.

See "Handling timeout and deadlock errors" on page 5-37 for a discussion about using this function.

Required privilege

```
XLA
```

Syntax

```
SQLRETURN ttXlaCommit(ttXlaHandle_h handle)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database

Returns

Returns `SQL_SUCCESS` if call is successful. Otherwise, use `ttXlaError` to report the error.

Example

```
rc = ttXlaCommit(xlahandle);
```

See also

ttXlaApply
ttXlaRollback
ttXlaLookup
ttXlaTableCheck
ttXlaGenerateSQL

ttXlaGenerateSQL

This function is part of XLA replication functionality and is not appropriate for use in a typical XLA application.

Note: This function does not currently work with LOB locators.

Description

Generates a SQL DML or DDL statement that expresses the effect of the update record. The generated statement is not applied to any database. Instead, the statement is returned in the given buffer, whose maximum size is specified by the *maxLen* parameter. The actual size of the buffer is returned in *actualLen*. For update and delete records, ttXlaGenerateSQL requires a primary key or a unique index on a non-nullable column to generate the correct SQL.

The generated SQL statement is encoded in the connection character set that is associated with the ODBC connection of the XLA handle.

Also see "Replicating updates to a non-TimesTen database" on page 5-38.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaGenerateSQL(ttXlaHandle_h handle,
                           ttXlaUpdateDesc_t* record,
                           out char* buffer,
                           SQLINTEGER maxLen,
                           out SQLINTEGER* actualLen)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
record	ttXlaUpdateDesc_t*	Record to be translated into SQL
buffer	char*	Location of the translated SQL statement
maxLen	SQLINTEGER	Maximum length of the buffer, in bytes
actualLen	SQLINTEGER*	Actual length of the buffer, in bytes

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

This example generates the text of a SQL statement that is equivalent to the UPDATE expressed by an update record:

```
ttXlaUpdateDesc_t record;
char buffer[200];
```

```
/*
 * Get the desired update record into the varable record.
 */

SQLINTEGER actualLength;

rc = ttXlaGenerateSQL(xlahandle, &record, buffer, 200,
                      &actualLength);
```

Note

The `ttXlaGenerateSQL` function cannot generate SQL statements for update records associated with a table that has been dropped or altered since the record was generated.

See also

ttXlaApply
ttXlaCommit
ttXlaRollback
ttXlaLookup
ttXlaTableCheck

ttXlaLookup

This function is part of XLA replication functionality and is not appropriate for use in a typical XLA application.

Description

This function looks for a record in the given table with key values according to the *keys* parameter. The formats of the *keys* and *result* records are the same as for ordinary rows. This function requires a primary key on the underlying table.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaLookup(ttXlaHandle_h handle,
                      ttXlaTableDesc_t* table,
                      void* keys,
                      out void* result,
                      SQLINTEGER maxsize,
                      out SQLINTEGER* retsize)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
table	ttXlaTblDesc_t*	Table to search
keys	void*	A record in the defined structure for the table
		Only those columns of the keys record that are part of the primary key for the table are examined.
result	void*	Where the located record is copied
		If no record exists with the matching key columns, an error is returned.
maxsize	SQLINTEGER	Size of the largest record that can fit into the result buffer
retsize	SQLINTEGER*	Actual size of the record

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

This example looks up a record given a pair of integer key values. Before this call, *table* should describe the desired table and *keybuffer* contains a record with the key columns set.

```
char keybuffer[100];
char recbuffer[2000];
ttXlaTableDesc_t table;
```

```
SQLINTEGER recordSize;

rc = ttXlaLookup(xlahandle, &table, keybuffer, recbuffer,
                 sizeof (recbuffer), &recordSize);
```

See also

ttXlaApply
ttXlaCommit
ttXlaRollback
ttXlaTableCheck
ttXlaGenerateSQL

ttXlaRollback

This function is part of XLA replication functionality and is not appropriate for use in a typical XLA application.

Description

Rolls back the current transaction being applied on the transaction log handle. You can call this routine to respond to transient errors (timeout or deadlock) reported by ttXlaApply.

See "Handling timeout and deadlock errors" on page 5-37 for a discussion about using this function.

Required privilege

XLA

Syntax

```
SQLRETURN ttXlaRollback(ttXlaHandle_h handle)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use ttXlaError to report the error.

Example

```
rc = ttXlaRollback(xlahandle);
```

See Also

ttXlaApply
ttXlaCommit
ttXlaLookup
ttXlaTableCheck
ttXlaGenerateSQL

ttXlaTableCheck

This function is part of XLA replication functionality and is not appropriate for use in a typical XLA application.

Description

When using XLA as a replication mechanism, this function verifies that the named table in the `ttXlaTblDesc_t` structure received from a master database is compatible with a subscriber database or database associated with the transaction log handle. The *compat* parameter indicates whether the tables are compatible.

See "Checking table compatibility between databases" on page 5-35 for a discussion about using this function.

Required privilege

```
XLA
```

Syntax

```
SQLRETURN ttXlaTableCheck(ttXlaHandle_h handle,
                          ttXlaTblDesc_t* table,
                          ttXlaColDesc_t* columns,
                          out SQLINTEGER* compat)
```

Parameters

Parameter	Type	Description
handle	ttXlaHandle_h	Transaction log handle for the database
table	ttXlaTblDesc_t*	Table description
columns	ttXlaColDesc_t*	Column description for the table
compat	SQLINTEGER*	Compatibility information:
		■ 1: Tables are compatible.
		■ 0: Tables are not compatible.

Returns

Returns SQL_SUCCESS if call is successful. Otherwise, use `ttXlaError` to report the error.

Example

This example checks the compatibility of a table:

```
SQLINTEGER compat;
ttXlaTblDesc_t table;
ttXlaColDesc_t columns[20];
/*
 * Get the desired table and column definitions into
 * the variables "table" and "columns"
 */
rc = ttXlaTableCheck(xlahandle, &table, columns, &compat);

C data structures used by XLA

This section describes the C data structures used by the XLA functions described in this chapter. These structures are defined in the following file:

install_dir/include/tt_xla.h

You must include this file when building your XLA application.

Table 9–1   Summary of C data structures

C data structure	Description
ttXlaNodeHdr_t	Describes the record type. Used at the beginning of records returned by XLA.
ttXlaUpdateDesc_t	Describes an update record.
ttXlaVersion_t	Describes XLA version information returned by ttXlaGetVersion.
ttXlaTblDesc_t	Describes table information returned by ttXlaGetTableInfo.
ttXlaTblVerDesc_t	Describes table version returned by ttXlaVersionTableInfo.
ttXlaColDesc_t	Describes table column information returned by ttXlaGetColumnInfo.
tt_LSN_t	Describes a log record identifier used by bookmarks. This structure is used by the ttXlaUpdateDesc_t structure.
tt_XlaLsn_t	Describes a log record identifier used by an XLA bookmark.

ttXlaNodeHdr_t

Most C data structures begin with a standard header that describes the data record type and length. The standard header has the type `ttXlaNodeHdr_t`.

This header has the following fields.

Field	Type	Description
nodeType	char	The type of record: ■ `TTXLANHVERSION`: Version ■ `TTXLANHUPDATE`: Update ■ `TTXLANHTABLEDESC`: Table description ■ `TTXLANHCOLDESC`: Column description ■ `TTXLANHSTATUS`: Status ■ `TTXLANHINVALID`: Invalid
byteOrder	char	Byte order of the record: ■ "1": Big-endian ■ "2": Little-endian
length	SQLUINTEGER	Total length of record, including all attachments

ttXlaUpdateDesc_t

This structure describes an update operation to a single row (or *tuple*) in the database. Each update record returned by a `ttXlaNextUpdate` or `ttXlaNextUpdateWait` function begins with a fixed length `ttXlaUpdateDesc_t` header followed by zero to two rows from the database. The row data differs depending on the record type reported in the `ttXlaUpdateDesc_t` header:

- No rows are present in a `COMMITONLY` record.

- One row is present in `INSERTTUP` or `DELETETUP`.

- Two rows are present in an `UPDATETUP` record to report the row data before and after the update, respectively.

- Special format rows are present in `CREATAB`, `DROPTAB`, `CREAIND`, `DROPIND`, `CREATVIEW`, `DROPVIEW`, `CREATSEQ`, `DROPSEQ`, `CREATSYN`, `DROPSYN`, `ADDCOLS`, and `DRPCOLS` records, which are described in "Special update data formats" on page 9-68.

The *flags* field is a bit-map of special options for the record update.

The *connID* field identifies the ODBC connection handle that initiated the update. This value can be used to determine if updates came from the same connection.

A separate commit XLA record is generated when a call to the `ttApplicationContext` procedure is not followed by an operation that generates an XLA record. See "Passing application context" on page 5-39 for a description of the `ttApplicationContext` procedure.

Note

XLA cannot receive notification of the following:

- `CREATE VIEW` or `DROP VIEW` for a non-materialized view

- `CREATE GLOBAL TEMPORARY TABLE` or `DROP TABLE` for a temporary table

The only XLA records that can be generated from an `ALTER TABLE` operation are of the following types:

- `ADDCOLS` or `DRPCOLS` when columns are added or dropped

- `CREAIND` or `DROPIND` when a unique attribute of a column is modified

While sequence creates (`CREATESEQ`) and drops (`DROPSEQ`) are visible through XLA, sequence increments are not.

All deletes resulting from cascading deletes and aging are visible through XLA. The *flags* value (discussed in the following table) indicates when deletes are due to cascading or aging.

The fields of the update header defined by `ttXlaUpdateDesc_t` are as follows.

Field	Type	Description
header	`ttXlaNodeHdr_t`	Standard data header

Field	Type	Description
type	SQLUSMALLINT	Record type:
		■ CREATAB: Create table.
		■ DROPTAB: Drop table.
		■ CREAIND: Create index.
		■ DROPIND: Drop index.
		■ CREATVIEW: Create view.
		■ DROPVIEW: Drop view.
		■ CREATSEQ: Create sequence.
		■ DROPSEQ: Drop sequence.
		■ CREATSYN: Create synonym.
		■ DROPSYN: Drop synonym.
		■ ADDCOLS: Add columns.
		■ DRPCOLS: Drop columns.
		■ TRUNCATE: Truncate table.
		■ INSERTTUP: Insert.
		■ UPDATETUP: Update.
		■ DELETETUP: Delete.
		■ COMMITONLY: Commit.

Field	Type	Description
flags	SQLUSMALLINT	Special options on record update:
		■ TT_UPDCOMMIT: Indicates that the update record is the last record for the transaction. (Implied commit.)
		■ TT_UPDFIRST: Indicates that the update record is the first record for the transaction.
		■ TT_UPDREPL: Indicates that this update was the result of a non-XLA TimesTen replicated update from another database.
		■ TT_UPDCOLS: Indicates the presence of a list following the last returned row that specifies which columns in the row were updated. The list consists of an array of SQLUSMALLINT values, the first of which is the number of columns that were updated, followed by the column numbers of the updated columns. For example, if the first and third columns are updated, the array is (2, 1, 3) or (2, 3, 1), depending on the UPDATE statement used. This array is in all UPDATETUP records.
		■ TT_UPDDEFAULT: Indicates that the update record (either a CREATAB or ADDCOLS) contains default column values. If set, the default columns are presented as an array of SQLUSMALLINT values followed by a string with all the default values concatenated. The number of SQLUSMALLINT values in the array equals the number of columns in the CREATAB or ADDCOLS record.
		■ TT_CASCDEL: Indicates that the XLA update was generated as part of a cascade delete operation.
		■ TT_AGING: Indicates that the XLA update was generated as part of an aging operation.
		If the value of a specific column is 0, it indicates that column does not have a default value. The defaults for all nonzero values are concatenated in a string and are presented in order, with the array value indicating the length of the default value. For example, three columns with defaults 1 of type INTEGER, no default, and "apple" of type VARCHAR2(10) is (1,0,5)"1apple".
		Decimal values for each of these *flags* bits is as follows. (Note that some flag values are for internal use only.)
		``` TT_UPDCOMMIT 1 TT_UPDFIRST 2 TT_UPDREPL 4 TT_UPDCOLS 8 TT_UPDDEFAULT 64 TT_CASCDEL 256 TT_AGING 512 ```
contextOffset	SQLUINTEGER	Offset to application-provided context value
		This value is 0 if there is no context. A nonzero value indicates the location of the context relative to the beginning of the XLA record.
connID	SQLUBIGINT	Connection ID owning the transaction
sysTableID	SQLUBIGINT	System-provided identifier of the affected table

Field	Type	Description
userTableID	SQLUBIGINT	Application-defined table ID of the affected table
tranID	SQLUBIGINT	Read-only, system-provided transaction identifier
LSN	tt_LSN_t	Transaction log record identifier of this operation, used for diagnostics
tuple1	SQLUINTEGER	Length of first row (tuple), or zero
tuple2	SQLUINTEGER	Length of second row (tuple), or zero

> **Note:** Be aware that tt_LSN_t, particularly the *logFile* and *logOffset* fields, is used differently than in earlier releases, referring to log record identifiers rather than sequentially increasing LSNs. See the note in "tt_LSN_t" on page 9-79.

Special update data formats

The data contained in an update record follows the ttXlaTblDesc_t header. This section describes the data formats for the special update records related to specific SQL operations.

CREATE TABLE

For a CREATE TABLE operation, the special row value consists of the ttXlaTblDesc_t record describing the new table, followed by the ttXlaColDesc_t records that describe each column.

ALTER TABLE

For an ALTER TABLE operation, the special row value consists of a ttXlaDropTableTup_t or ttXlaAddColumnTup_t value, followed by a ttXlaColDesc_t record that describes the column.

ttXlaDropTableTup_t

For a DROP TABLE operation, the row value is as follows.

Field	Type	Description
tblName	char(31)	Name of the dropped table
tblOwner	char(31)	Owner of the dropped table

ttXlaTruncateTableTup_t

For a TRUNCATE TABLE operation, the row value is as follows.

Field	Type	Description
tblName	char(31)	Name of the truncated table
tblOwner	char(31)	Owner of the truncated table

ttXlaCreateIndexTup_t

For a CREATE INDEX operation, the row value is as follows.

Field	Type	Description
tblName	char(31)	Name of the table on which the index is defined
tblOwner	char(31)	Owner of the table on which the index is defined
ixName	char(31)	Name of the new index
flag	char(31)	Index flag: ■ "P": Primary key ■ "F": Foreign key ■ "R": Regular
nixcols	SQLUINTEGER	Number of indexed columns
ixColsSys	SQLUINTEGER(16)	Indexed column numbers using system numbers
ixColsUser	SQLUINTEGER(16)	Indexed column numbers using user-defined column IDs
ixType	char	Type of index: ■ "T": Range ■ "H": Hash ■ "B": Bit map
ixUnique	char	Uniqueness of index: ■ "U": Unique ■ "N": Non-unique
pages	SQLUINTEGER	Number of pages for hash indexes

ttXlaDropIndexTup_t
For a DROP INDEX operation, the row value is as follows.

Field	Type	Description
tblName	char(31)	Name of the table on which the index was dropped
tblOwner	char(31)	Owner of the table on which the index was dropped
ixName	char(31)	Name of the dropped index

ttXlaAddColumnTup_t
For an ADD COLUMN operation, the row value is as follows.

Field	Type	Description
ncols	SQLUINTEGER	Number of additional columns

Following this special row are the ttXlaColDesc_t records describing the new columns.

ttXlaDropColumnTup_t
For a DROP COLUMN operation, the row value is as follows.

Field	Type	Description
ncols	SQLUINTEGER	Number of dropped columns

Following this special row is an array of ttXlaColDesc_t records describing the columns that were dropped.

ttXlaCreateSeqTup_t

For a CREATE SEQUENCE operation, the row value is as follows.

Field	Type	Description
sqName	char(31)	Name of sequence
sqOwner	char(31)	Owner of sequence
cycle	char	Cycle flag
		Indicates whether the sequence number generator will continue to generate numbers after it reaches the maximum or minimum value:
		■ "1": Yes
		■ "0": No
minval	SQLBIGINT	Minimum value of sequence
maxval	SQLBIGINT	Maximum value of sequence
incr	SQLBIGINT	Increment between sequence numbers
		Positive numbers indicate an ascending sequence and negative numbers indicate a descending sequence. In a descending sequence, the range goes from *maxval* to *minval*. In an ascending sequence, the range goes from *minval* to *maxval*.

ttXlaDropSeqTup_t

For a DROP SEQUENCE operation, the row value is as follows.

Field	Type	Description
sqName	char(31)	Name of sequence
sqOwner	char(31)	Owner of sequence

ttXlaViewDesc_t

For a CREATE VIEW operation, the row value is as follows.

> **Note:** This applies to either materialized or non-materialized views.

Field	Type	Description
vwName	char(31)	Name of view
vwOwner	char(31)	Owner of view
sysTableID	SQLUBIGINT	System table ID stored in SYS.TABLES

ttXlaDropViewTup_t

For a DROP VIEW operation, the row value is as follows.

> **Note:** This applies to either materialized or non-materialized views.

Field	Type	Description
vwName	char(31)	Name of view
vwOwner	char(31)	Owner of view

ttXlaCreateSynTup_t

For a CREATE SYNONYM operation, the row value is as follows.

Field	Type	Description
synName	char(31)	Name of synonym
synOwner	char(31)	Owner of synonym
objName	char(31)	Name of object the synonym points to
objOwner	char(31)	Owner of object the synonym points to
isPublic	char	Indicates whether the synonym is public: ■ "1": True ■ "0": False
isReplace	char	Indicates whether the synonym was created using CREATE OR REPLACE: ■ "1": True ■ "0": False

ttXlaDropSynTup_t

For a DROP SYNONYM operation, the row value is as follows.

Field	Type	Description
synName	char(31)	Name of synonym
synOwner	char(31)	Owner of synonym
isPublic	char	Indicates whether the synonym is public: ■ "1": True ■ "0": False

ttXlaSetTableTup_t

The description of the SET TABLE ID operation uses the previously assigned application table identifier in the main part of the update record and provides the new value of the application table identifier in the following special row.

Field	Type	Description
newID	SQLUBIGINT	New user-defined table ID

ttXlaSetColumnTup_t

The description of the SET COLUMN ID operation provides the following special row:

Field	Type	Description
oldUserColID	SQLUINTEGER	Previous user-defined column ID value
newUserColID	SQLUINTEGER	New user-defined column ID value
sysColID	SQLUINTEGER	System column ID

ttXlaSetStatusTup_t

A change in a table's replication status provides the following special row:

Field	Type	Description
oldStatus	SQLUINTEGER	Previous replication status
newStatus	SQLUINTEGER	New replication status

Locating the row data following a ttXlaUpdateDesc_t header

See "Retrieving update records from the transaction log" on page 5-13 and "Inspecting record headers and locating row addresses" on page 5-15 for a detailed discussion on obtaining update records and inspecting the contents of ttXlaUpdateDesc_t headers. Below is a summary of these procedures.

The update header is immediately followed by the row data. The row data is stored in an internal format with the offsets given in the ttXlaColDesc_t structure returned by ttXlaGetColumnInfo.

You can locate the address of the row data by adding the address of the update header to its size.

For example:

```
char* Row = (char*)&ttXlaUpdateDesc_t +
            sizeof(ttXlaUpdateDesc_t);
```

For UPDATETUP records, there are two rows of data following the ttXlaUpdateDesc_t header. The first row contains the data before the update, and the second row the data after the update.

Since the new row is right after the old row, you can calculate its address by adding the address of the old row to its length (tuple1).

For example:

```
char* oldRow = (char*)&ttXlaUpdateDesc_t +
               sizeof(ttXlaUpdateDesc_t);
char* newRow = oldRow + ttXlaUpdateDesc_t.tuple1;
```

See "ttXlaColDesc_t" on page 9-76 for details on how to access the column data in a returned row.

ttXlaVersion_t

To permit future extensions to XLA, a version structure `ttXlaVersion_t` describes the current XLA version and structure byte order. This structure is returned by the `ttXlaGetVersion` function.

This structure has the following fields:

Field	Type	Description
header	ttXlaNodeHdr_t	Standard data header
hardware	char(16)	Name of hardware platform
wordSize	SQLUINTEGER	Native word size (32 or 64)
TTMajor	SQLUINTEGER	TimesTen major version
TTMinor	SQLUINTEGER	TimesTen minor version
TTPatch	SQLUINTEGER	TimesTen point release number
OS	char(16)	Name of operating system
OSMajor	SQLUINTEGER	Operating system major version
OSMinor	SQLUINTEGER	Operating system minor version

ttXlaTblDesc_t

Table information is portrayed through the ttXlaTblDesc_t structure. This structure is returned by the ttXlaGetTableInfo function.

This structure has the following fields:

Field	Type	Description
header	ttXlaNodeHdr_t	Standard data header
tblName	char(31)	Name of the table, null-terminated
tblOwner	char(31)	Owner of the table, null-terminated
sysTableID	SQLUBIGINT	Unique system-defined table identifier
userTableId	SQLUBIGINT	User-defined table identifier
columns	SQLUINTEGER	Number of columns
width	SQLUINTEGER	Inline row size
nPrimCols	SQLUINTEGER	Number of primary columns
primColsSys	SQLUINTEGER(16)	System primary key column numbers
primColsUser	SQLUINTEGER(16)	User-defined primary key column numbers

The inline row size includes space for all fixed-width columns, null column flags, and pointer information for variable-length columns. Each varying-length column occupies four bytes of inline row space.

Note the following if the table has a declared primary key:

- The *nPrimCols* value is greater than 0.

- The *primColsSys* array contains the column numbers of the primary key, in the same order in which they were originally declared with the CREATE TABLE statement.

- The *primColsUser* array contains the corresponding application-specified column identifiers.

ttXlaTblVerDesc_t

This data structure contains the table version number and `ttXlaTblDesc_t`. It is returned by `ttXlaVersionTableInfo`. This structure has the following fields:

Field	Type	Description
tblDesc	ttXlaTblDesc_t	Table description
tblVer	SQLBIGINT	System-generated table version number

ttXlaColDesc_t

Column information is given through this structure, which is returned by the ttXlaGetColumnInfo function.

The structure has the following fields:

Field	Type	Description
header	ttXlaNodeHdr_t	Standard data header
colName [tt_NameLenMax]	char	Name of the column
pad0	SQLUINTEGER	Pad to four-byte boundary
sysColNum	SQLUINTEGER	Ordinal number of the column as determined when the table is created or subsequently altered
		This is the same as the corresponding COLNUM value in SYS.COLUMNS. (See "SYS.COLUMNS" in *Oracle TimesTen In-Memory Database System Tables and Views Reference*.)
userColNum	SQLUINTEGER	Ordinal number of the column if optionally specified by the user
		This is zero or a column number specified through the ttSetUserColumnID TimesTen built-in procedure. (See "ttSetUserColumnID" in *Oracle TimesTen In-Memory Database Reference*.)
dataType	SQLUINTEGER	Structure in ODBC TTXLA_* code
		See "About XLA data types" on page 5-7.
size	SQLUINTEGER	Maximum or basic size of column
offset	SQLUINTEGER	Offset to fixed-length part of column
nullOffset	SQLUINTEGER	Offset to null byte, or zero if not nullable
precision	SQLSMALLINT	Numeric precision for decimal types
scale	SQLSMALLINT	Numeric scale for decimal types
flags	SQLUINTEGER	Column flag:
		■ TT_COLPRIMKEY: Column is primary key.
		■ TT_COLVARYING: Column is stored out of line.
		■ TT_COLNULLABLE: Column is nullable.
		■ TT_COLUNIQUE: Column has a unique attribute defined on it.

The procedures for obtaining a ttXlaColDesc_t structure and inspecting its contents are described in "Inspecting column data" on page 5-17. Below is a summary of these procedures.

The ttXlaColDesc_t structure is returned by the ttXlaGetColumnInfo function. This structure contains the metadata needed to access column information in a particular

table. For example, you can use the *offset* field to locate specific column data in the row or rows returned in an update record after the `ttXlaColDesc_t` structure. By adding the *offset* to the address of a returned row, you can locate the address to the column value. You can then cast this value to the corresponding C types according to the *dataType* field, or pass it to one of the conversion routines described in "Converting complex data types" on page 5-23.

TimesTen row data consists of fixed-length data followed by any variable-length data.

- For fixed length column data, `ttXlaColDesc_t` returns the *offset* and *size* of the column data. The *offset* is relative to the beginning of the fixed part of the record. See Example 9–1 below.

- For variable-length column data (`VARCHAR2`, `NVARCHAR2`, and `VARBINARY`), *offset* is an address that points to a four-byte offset value. By adding the offset address to the offset value, you can obtain the address of the column data in the variable-length portion of the row. The first *n* bytes at this location is the length of the data, followed by the actual data (where *n* is 4 on 32-bit platforms or 8 on 64-bit platforms). For variable-length data, the returned size value is the maximum allowable column size. See Example 9–1 below.

For columns that can have null values, *nullOffset* points to a null byte in the record. This value is 1 if the column is null, or 0 if it is not null. See "Detecting null values" on page 5-25 for a discussion.

The *flags* bits define whether the column is nullable, part of a primary key, or stored out of line.

The *sysColNum* value is the system column number to assign to the column. This value begins with 1 for the first column.

Note: LOB support in XLA is limited, as follows:

- You can subscribe to tables containing LOB columns, but information about the LOB value itself is unavailable.

- `ttXlaGetColumnInfo` returns information about LOB columns.

- Columns containing LOBs are reported as empty (zero length) or null (if the value is actually `NULL`). In this way, you can tell the difference between a null column and a non-null column.

Example 9–1   Copying and printing a VARCHAR2 string

For fixed-length column data, the address of a column is the *offset* value in the `ttXlaColDesc_t` structure, plus the address of the row as follows:

```
ttXlaColDesc_t colDesc;

void* pColVal = colDesc->offset + row;
```

The value of the column can be obtained by dereferencing this pointer using a type pointer that corresponds to the data type. For example, for `SQL_INTEGER`, the ODBC type is `SQLINTEGER` and the value of the column can be obtained by the following:

```
*((SQLINTEGER*) pColVal))
```

In the case of variable-length column data, the *pColVal* calculated above is the address of a four-byte offset value. Adding this offset value to the address of *pColVal* provides a pointer to the beginning of the variable-length column data. Assuming the operation

is performed on a 64-bit platform, the first eight bytes at this location is the length of this data (var_len), followed by the actual data (var_data).

In this example, a VARCHAR string is copied and printed.

```
tt_ptrint* var_len = (tt_ptrint*)((char*)pColVal +
                       *((int*)pColVal));
char* var_data = (char*)(var_len+1);
char* buffer = malloc(*var_len+1);
memcpy(buffer,var_data,*var_len);
buffer[*var_len] = (char)NULL; /* NULL terminate the string */
printf("%s\n",buffer);
free(buffer);
```

tt_LSN_t

Description of log record identifier used by bookmarks. This structure is used by the ttXlaUpdateDesc_t structure.

Field	Type	Description
logFile	SQLUBIGINT	Higher order portion of log record identifier
logOffset	SQLUBIGINT	Lower order portion of log record identifier

> **Note:** The *logFile* and *logOffset* field names are retained for backward compatibility, although their usage has changed. In previous releases the values referred to LSNs, which increased sequentially, and the values had very specific meanings, indicating the log file number plus byte offset. Now they refer to log record identifiers, which are more abstract and do not have a direct relationship to the log file number and byte offset. All you can assume about a sequence of log record identifiers is that a log record identifier B read at a later time than a log record identifier A will have a higher value.

tt_XlaLsn_t

Description of a log record identifier used by bookmarks. This structure is returned by the ttXlaGetLSN function and used by the ttXlaSetLSN function.

The *checksum* is specific to an XLA handle to ensure that every log record identifier is related to a known XLA connection.

Field	Type	Description
checksum	SQLUINTEGER	Checksum used to ensure that it is a valid log record identifier handle
xid	SQLUSMALLINT	Transaction ID
logFile	SQLUBIGINT	Higher order portion of log record identifier
logOffset	SQLUBIGINT	Lower order portion of log record identifier

> **Note:** The *logFile* and *logOffset* field names are retained for backward compatibility, although their usage has changed. In previous releases the values referred to LSNs, which increased sequentially, and the values had very specific meanings, indicating the log file number plus byte offset. Now they refer to log record identifiers, which are more abstract and do not have a direct relationship to the log file number and byte offset. All you can assume about a sequence of log record identifiers is that a log record identifier B read at a later time than a log record identifier A will have a higher value.

TimesTen ODBC Functions and Options

This chapter covers the topics noted below, listing ODBC functions supported by TimesTen and options supported by TimesTen for set and get functions for statements and connections. For complete function definitions, refer to ODBC API reference documentation.

TimesTen supports ODBC 2.5, Extension Level 1, as well as Extension Level 2 features that are documented in this chapter.

- Supported ODBC functions

- Option support for ODBC connection and statement functions

- Information type support for SQLGetInfo

- Column descriptor support for SQLColAttributes

Supported ODBC functions

This section lists ODBC function supported by TimesTen, with special notes as applicable.

Table 10–1   Supported ODBC functions

Function	Notes for TimesTen
SQLAllocConnect	
SQLAllocEnv	
SQLAllocStmt	
SQLBindCol	
SQLBindParameter	See "SQLBindParameter function" on page 2-12.
SQLCancel	SQLCancel can cancel the following: ■ An operation running on an *hstmt* on another thread ■ An operation running on an *hstmt* that needs data SQLCancel *cannot* cancel the following: ■ A global query SQLCancel can cancel only on the local node. ■ In Memory Database Cache or cache grid administrative operations Do not call SQLCancel directly from a signal handler. Such code may not be portable.

Table 10–1   (Cont.) Supported ODBC functions

Function	Notes for TimesTen
`SQLColAttributes` and `SQLColAttributesW`	See "Column descriptor support for SQLColAttributes" on page 10-8.
`SQLColumns` and `SQLColumnsW`	
`SQLConnect`	
`SQLDataSources` and `SQLDataSourcesW`	Available only to programs using a driver manager.
`SQLDescribeCol` and `SQLDescribeColW`	
`SQLDescribeParam`	
`SQLDisconnect`	
`SQLDriverConnect` and `SQLDriverConnectW`	
`SQLDrivers` and `SQLDriversW`	Available only to programs using a driver manager.
`SQLError` and `SQLErrorW`	Native error codes are TimesTen errors. You may receive generic errors such as, "Execution at Oracle failed. Oracle error code *nnn*."
`SQLExecDirect`	See the note for `SQLExecute`.
`SQLExecute`	TimesTen does not support asynchronous statement execution. (TimesTen does not support the `SQL_ASYNC_ENABLE` statement option, as noted later in this chapter.)
`SQLFetch`	
`SQLForeignKeys` and `SQLForeignKeysW`	
`SQLFreeConnect`	
`SQLFreeEnv`	
`SQLFreeStmt`	
`SQLGetConnectOption` and `SQLGetConnectOptionW`	See "Option support for SQLSetConnectOption and SQLGetConnectOption" on page 10-3.
`SQLGetCursorName` and `SQLGetCursorNameW`	You can set or get a cursor name but not reference it, such as in a `WHERE CURRENT OF` clause for a positioned update or delete. TimesTen does not support positioned update or delete statements.
`SQLGetData`	See "Avoid SQLGetData" on page 7-2.
`SQLGetFunctions`	
`SQLGetInfo` and `SQLGetInfoW`	See "Information type support for SQLGetInfo" on page 10-7.
`SQLGetStmtOption`	See "Option support for SQLSetStmtOption and SQLGetStmtOption" on page 10-5.
`SQLGetTypeInfo` and `SQLGetTypeInfoW`	
`SQLNativeSql` and `SQLNativeSqlW`	
`SQLNumParams`	
`SQLNumResultCols`	
`SQLParamData`	

Table 10–1   (Cont.) Supported ODBC functions

Function	Notes for TimesTen
`SQLParamOptions`	
`SQLPrepare`	
`SQLPrimaryKeys` and `SQLPrimaryKeysW`	
`SQLProcedureColumns` and `SQLProcedureColumnsW`	
`SQLProcedures` and `SQLProceduresW`	
`SQLPutData`	
`SQLRowCount`	In addition to its standard functionality, this has special usage with cache groups. See "Managing cache groups" on page 2-31.
`SQLSetConnectOption` and `SQLSetConnectOptionW`	See "Option support for SQLSetConnectOption and SQLGetConnectOption" under the next section.
`SQLSetCursorName` and `SQLSetCursorNameW`	You can set or get a cursor name but not reference it, such as in a `WHERE CURRENT OF` clause for a positioned update or delete.
`SQLSetStmtOption`	See "Option support for SQLSetStmtOption and SQLGetStmtOption" on page 10-5.
`SQLSetParam`	This is an ODBC 1.0 function, replaced by `SQLBindParameter` in ODBC 2.0. Retained for backward compatibility.
`SQLSpecialColumns` and `SQLSpecialColumnsW`	
`SQLStatistics` and `SQLStatisticsW`	
`SQLTables` and `SQLTablesW`	
`SQLTransact`	

Note: TimesTen supports only UTF-16 as a national character set.

Option support for ODBC connection and statement functions

This section discusses TimesTen option support for the ODBC functions `SQLSetConnectOption`, `SQLGetConnectOption`, `SQLSetStmtOption`, and `SQLGetStmtOption`.

Refer to ODBC API reference documentation for general information about these functions.

Option support for SQLSetConnectOption and SQLGetConnectOption

Table 10–2 and Table 10–3 document TimesTen support for standard and TimesTen-specific options for the ODBC `SQLSetConnectOption` and `SQLGetConnectOption` functions. These functions let you set connection options after the initial connection or retrieve those settings. Some of these correspond to connection attributes you can set during the connection process, as noted.

Also see "Option support for SQLSetStmtOption and SQLGetStmtOption" on page 10-5. Those options can also be set using `SQLSetConnectOption`, in which case the value serves as a default for all statements on the connection.

> **Notes:**
>
> - An option setting through `SQLSetConnectOption` or `SQLSetStmtOption` overrides the setting of the corresponding connection attribute (as applicable).
>
> - The documentation here also applies to `SQLSetConnectOptionW` and `SQLGetConnectOptionW`.

Table 10–2   Standard options: SQLSetConnectOption, SQLGetConnectOption

Option	Support
SQL_ACCESS_MODE	No
SQL_AUTOCOMMIT	Yes
SQL_CURRENT_QUALIFIER	No
SQL_LOGIN_TIMEOUT	No
SQL_MAX_ROWS	Yes
SQL_NOSCAN	Yes
SQL_ODBC_CURSORS	Yes, for programs using a driver manager
SQL_OPT_TRACE	Yes, for programs using a driver manager
SQL_OPT_TRACEFILE	Yes, for programs using a driver manager
SQL_PACKET_SIZE	No
SQL_QUIET_MODE	No
SQL_TRANSLATE_DLL	No
SQL_TRANSLATE_OPTION	No
SQL_TXN_ISOLATION	Yes, if *vParam* is SQL_TXN_READ_COMMITTED or SQL_TXN_SERIALIZABLE See "Prefetching multiple rows of data" on page 2-11. Also see "Concurrency control through isolation and locking" in *Oracle TimesTen In-Memory Database Operations Guide*. Same functionality as the `Isolation` general connection attribute, as described in "Isolation" in *Oracle TimesTen In-Memory Database Reference*.

Table 10–3   TimesTen options: SQLSetConnectOption, SQLGetConnectOption

Option	Comments
TT_CLIENT_TIMEOUT	This is for client/server only and has the same functionality as the `TTC_Timeout` TimesTen client connection attribute, as described in "TTC_Timeout" in *Oracle TimesTen In-Memory Database Reference*.

Table 10–3   (Cont.) TimesTen options: SQLSetConnectOption, SQLGetConnectOption

Option	Comments
`TT_DYNAMIC_LOAD_ENABLE`	See "Dynamic load configuration" in *Oracle In-Memory Database Cache User's Guide*. This has the same functionality as the `DynamicLoadEnable` IMDB Cache general connection attribute described in "DynamicLoadEnable" in *Oracle TimesTen In-Memory Database Reference*.
`TT_DYNAMIC_LOAD_ERROR_MODE`	See "Return dynamic load errors" in *Oracle In-Memory Database Cache User's Guide*. This has the same functionality as the `DynamicLoadErrorMode` IMDB Cache connection attribute described in "DynamicLoadErrorMode" in *Oracle TimesTen In-Memory Database Reference*.
`TT_NLS_LENGTH_SEMANTICS`	See "Setting globalization options" on page 2-31. This has the same functionality as the `NLS_LENGTH_SEMANTICS` general connection attribute described in "NLS_LENGTH_SEMANTICS" in *Oracle TimesTen In-Memory Database Reference*. There is also related information about the functionality in "Additional globalization features" on page 3-4.
`TT_NLS_NCHAR_CONV_EXCP`	See "Setting globalization options" on page 2-31. This has the same functionality as the `NLS_NCHAR_CONV_EXCP` general connection attribute described in "NLS_NCHAR_CONV_EXCP" in *Oracle TimesTen In-Memory Database Reference*. There is also related information about the functionality in "Additional globalization features" on page 3-4.
`TT_NLS_SORT`	See "Setting globalization options" on page 2-31. This has the same functionality as the `NLS_SORT` general connection attribute described in "NLS_SORT" in *Oracle TimesTen In-Memory Database Reference*. There is also related information about the functionality in "Additional globalization features" on page 3-4.
`TT_PREFETCH_CLOSE`	See "Enable TT_PREFETCH_CLOSE for Serializable transactions" in *Oracle TimesTen In-Memory Database Operations Guide*.
`TT_REGISTER_FAILOVER_CALLBACK`	See "Using automatic client failover in your application" on page 2-36.
`TT_REPLICATION_TRACK`	See "Features for use with replication" on page 2-32. This has the same functionality as the `ReplicationTrack` general connection attribute, to specify a track number for the connection in user-defined parallel replication.

Option support for SQLSetStmtOption and SQLGetStmtOption

Table 10–4 and Table 10–5 document TimesTen support for standard and TimesTen-specific options for the ODBC `SQLSetStmtOption` and `SQLGetStmtOption` functions, which let you set or retrieve statement option settings.

To set an option default value for all statements associated with a connection, use `SQLSetConnectOption`.

> **Notes:** An option setting through `SQLSetConnectOption` or `SQLSetStmtOption` overrides the setting of the corresponding connection attribute (as applicable).

Table 10–4   Standard options: SQLSetStmtOption, SQLGetStmtOption

Option	Support
SQL_ASYNC_ENABLE	No
SQL_BIND_TYPE	No
SQL_CONCURRENCY	No
SQL_CURSOR_TYPE	No
SQL_KEYSET_SIZE	No
SQL_MAX_LENGTH	No SQL_MAX_LENGTH can be set, but any specified value will be overridden with 0 (return all available data).
SQL_MAX_ROWS	Yes
SQL_NOSCAN	Yes
SQL_QUERY_TIMEOUT	Yes See "Setting a timeout or threshold for executing SQL statements" on page 2-29.
SQL_RETRIEVE_DATA	No
SQL_ROWSET_SIZE	No
SQL_SIMULATE_CURSOR	No
SQL_USE_BOOKMARKS	No

Table 10–5   TimesTen options: SQLSetStmtOption, SQLGetStmtOption

Option	Comment
TT_PREFETCH_COUNT	See "Prefetching multiple rows of data" on page 2-11.
TT_QUERY_THRESHOLD	See "Setting a threshold duration for SQL statements" on page 2-30. This is to specify a time threshold for SQL statements, in seconds, after which TimesTen will write a warning to the support log and throw an SNMP trap.
TT_PRIVATE_COMMANDS	Commands are not shared with any other connection. See "PrivateCommands" in *Oracle TimesTen In-Memory Database Reference*.

Table 10–5   (Cont.) TimesTen options: SQLSetStmtOption, SQLGetStmtOption

Option	Comment
TT_STMT_PASSTHROUGH_TYPE	Determines whether a specific prepared statement will be passed through to Oracle by the passthrough feature of IMDB Cache. The value returned by SQLGetStmtOption can be either TT_STMT_PASSTHROUGH_NONE or TT_STMT_PASSTHROUGH_ORACLE.
	Note: In TimesTen, this option is supported only with SQLGetStmtOption.
	See "Determining passthrough status" on page 2-31. Also see "Setting a passthrough level" in *Oracle In-Memory Database Cache User's Guide*.

Information type support for SQLGetInfo

This section covers standard and TimesTen-specific information types supported by TimesTen for the ODBC function SQLGetInfo.

Refer to ODBC API reference documentation for general information about this function and standard information types.

TimesTen supports the following standard ODBC 2.x information types (in alphabetical order):

```
SQL_ACCESSIBLE_PROCEDURES, SQL_ACCESSIBLE_TABLES, SQL_ACTIVE_CONNECTIONS,
SQL_ACTIVE_STATEMENTS, SQL_ALTER_TABLE, SQL_BOOKMARK_PERSISTENCE,
SQL_COLUMN_ALIAS, SQL_CONCAT_NULL_BEHAVIOR, SQL_CONVERT_BIGINT,
SQL_CONVERT_BINARY, SQL_CONVERT_BIT, SQL_CONVERT_CHAR, SQL_CONVERT_DATE,
SQL_CONVERT_DECIMAL, SQL_CONVERT_DOUBLE, SQL_CONVERT_FLOAT,
SQL_CONVERT_FUNCTIONS, SQL_CONVERT_INTEGER, SQL_CONVERT_LONGVARBINARY,
SQL_CONVERT_LONGVARCHAR, SQL_CONVERT_NUMERIC, SQL_CONVERT_REAL,
SQL_CONVERT_SMALLINT, SQL_CONVERT_TIME, SQL_CONVERT_TIMESTAMP,
SQL_CONVERT_TINYINT, SQL_CONVERT_VARBINARY, SQL_CONVERT_VARCHAR,
SQL_CONVERT_WVARCHAR, SQL_CORRELATION_NAME, SQL_CURSOR_COMMIT_BEHAVIOR,
SQL_CURSOR_ROLLBACK_BEHAVIOR, SQL_DATA_SOURCE_NAME, SQL_DATA_SOURCE_READ_ONLY,
SQL_DATABASE_NAME, SQL_DBMS_NAME, SQL_DBMS_VER, SQL_DEFAULT_TXN_ISOLATION,
SQL_DRIVER_HDBC, SQL_DRIVER_HENV, SQL_DRIVER_HLIB, SQL_DRIVER_HSTMT,
SQL_DRIVER_NAME, SQL_DRIVER_ODBC_VER, SQL_DRIVER_VER, SQL_EXPRESSIONS_IN_ORDERBY,
SQL_FETCH_DIRECTION, SQL_FILE_USAGE, SQL_GETDATA_EXTENSIONS, SQL_GROUP_BY,
SQL_IDENTIFIER_CASE, SQL_IDENTIFIER_QUOTE_CHAR, SQL_KEYWORDS,
SQL_LIKE_ESCAPE_CLAUSE, SQL_LOCK_TYPES, SQL_MAX_BINARY_LITERAL_LEN,
SQL_MAX_CHAR_LITERAL_LEN, SQL_MAX_COLUMN_NAME_LEN, SQL_MAX_COLUMNS_IN_GROUP_BY,
SQL_MAX_COLUMNS_IN_INDEX, SQL_MAX_COLUMNS_IN_ORDER_BY, SQL_MAX_COLUMNS_IN_SELECT,
SQL_MAX_COLUMNS_IN_TABLE, SQL_MAX_CURSOR_NAME_LEN, SQL_MAX_INDEX_SIZE,
SQL_MAX_OWNER_NAME_LEN, SQL_MAX_PROCEDURE_NAME_LEN, SQL_MAX_QUALIFIER_NAME_LEN,
SQL_MAX_ROW_SIZE, SQL_MAX_ROW_SIZE_INCLUDES_LONG, SQL_MAX_STATEMENT_LEN,
SQL_MAX_TABLE_NAME_LEN, SQL_MAX_TABLES_IN_SELECT, SQL_MAX_USER_NAME_LEN,
SQL_MULT_RESULT_SETS, SQL_MULTIPLE_ACTIVE_TXN, SQL_NEED_LONG_DATA_LEN,
SQL_NON_NULLABLE_COLUMNS, SQL_NULL_COLLATION, SQL_NUMERIC_FUNCTIONS,
SQL_ODBC_API_CONFORMANCE, SQL_ODBC_SAG_CLI_CONFORMANCE, SQL_ODBC_SQL_CONFORMANCE,
SQL_ODBC_SQL_OPT_IEF, SQL_ODBC_VER, SQL_OJ_CAPABILITIES,
SQL_ORDER_BY_COLUMNS_IN_SELECT, SQL_OUTER_JOINS, SQL_OWNER_TERM, SQL_OWNER_USAGE,
SQL_POS_OPERATIONS, SQL_POSITIONED_STATEMENTS, SQL_PROCEDURE_TERM,
SQL_PROCEDURES, SQL_QUALIFIER_LOCATION, SQL_QUALIFIER_NAME_SEPARATOR,
SQL_QUALIFIER_TERM, SQL_QUALIFIER_USAGE, SQL_QUOTED_IDENTIFIER_CASE,
SQL_ROW_UPDATES, SQL_SCROLL_CONCURRENCY, SQL_SCROLL_OPTIONS,
SQL_SEARCH_PATTERN_ESCAPE, SQL_SERVER_NAME, SQL_SPECIAL_CHARACTERS,
```

```
SQL_STATIC_SENSITIVITY, SQL_STRING_FUNCTIONS, SQL_SUBQUERIES,
SQL_SYSTEM_FUNCTIONS, SQL_TABLE_TERM, SQL_TIMEDATE_ADD_INTERVALS,
SQL_TIMEDATE_DIFF_INTERVALS, SQL_TIMEDATE_FUNCTIONS, SQL_TXN_CAPABLE,
SQL_TXN_ISOLATION_OPTION, SQL_UNION, SQL_USER_NAME
```

> **Note:** `SQL_DRIVER_HLIB` is supported with a driver manager only.

TimesTen supports the following standard ODBC 3.x information types:

```
SQL_AGGREGATE_FUNCTIONS, SQL_CONVERT_WCHAR, SQL_CONVERT_WLONGVARCHAR,
SQL_CREATE_VIEW, SQL_DATETIME_LITERALS, SQL_DROP_VIEW,
SQL_SQL92_RELATIONAL_JOIN_OPERATORS, SQL_SQL92_VALUE_EXPRESSIONS
```

Table 10–6 describes TimesTen-specific information types.

Table 10–6   TimesTen information items: SQLGetInfo

Information type	Data type	Description
`TT_DATA_STORE_INVALID`	`SQLINTEGER`	Returns 1 if the database is in invalid state, such as due to a system or application failure, or 0 if not.
		Note: Fatal errors, such as error 846 or 994, invalidate a TimesTen database, causing this item to be set to 1.
`TT_DATABASE_CHARACTER_SET`	`SQLCHAR`	Returns the name of the database character set.
`TT_DATABASE_CHARACTER_SET_SIZE`	`SQLINTEGER`	Returns the maximum size of a character in the database character set, in bytes.
`TT_DATABASE_TYPE_MODE`	`SQLINTEGER`	Returns 0 for Oracle type mode (typical and default setting), or 1 for TimesTen type mode (legacy setting).
		Note: The type mode can be specified through the `TypeMode` connection attribute.
`TT_PLATFORM_INFO`	Bit mask	Returns a bit mask indicating platform information. Bit 0 has the value 1 for a 64-bit platform, or the value 0 for a 32-bit platform. Bit 1 has the value 1 for big-endian, or the value 0 for little-endian.
`TT_REPLICATION_INVALID`	`SQLINTEGER`	Returns 1 if replication is in a failed state, or 0 if not.

Column descriptor support for SQLColAttributes

This section covers TimesTen-specific column descriptor information supported for the ODBC function `SQLColAttributes`.

Refer to ODBC API reference documentation for general information about this function and standard information types.

Table 10–7 describes TimesTen-specific column descriptors.

Table 10–7   TimesTen column descriptors: SQLColAttributes

Descriptor	Comment/description
TT_COLUMN_INLINE	Returns TRUE for columns with inline data, or FALSE otherwise. This is returned in the SQLColAttributes *pfDesc* parameter.
TT_COLUMN_LENGTH_SEMANTICS	For character-type columns, this returns "BYTE" for columns with byte length semantics and "CHAR" for columns with character length semantics. For non-character columns, it returns "". The information is returned in the SQLColAttributes *rgbDesc* parameter. This information refers to whether data length is measured in bytes or characters. Length semantics in TimesTen are the same as in Oracle Database. See "Length Semantics" in *Oracle Database Globalization Support Guide* for additional information.
